It is generally agreed that reduced cytochrome *c* ows absorption bands in the visible spectrum at 0 mμ (α-band) and at 520 mμ (β-band); in fact, e presence of these two absorption bands is the incipal means of detecting reduced cytochrome *c* a biological object. Keilin and Hartree[1] have served the absorption bands of cytochrome *c* solved in 50 per cent glycerol and in the vitrified devitrified states at the temperature of liquid air oxygen, a procedure by which the absorption bands n be intensified and sharpened; under these nditions they report that a fine satellite band pears next to the α-band on its short-wave side, d the β-band appears to be a complex of several aks. In connexion with studies on the cytochrome sorption bands of Protozoa[2], we have examined e absorption bands of two commercial preparations cytochrome *c* (beef heart, salt-free, Sigma Chemical .; Boehringer und Söhne, Mannheim) using the liquid-air cooling technique of Keilin and Hartree. A 0·07 per cent (w/v) solution of Sigma cytochrome *c* and a 0·2 per cent (w/v) of Boehringer cytochrome *c* in 70 per cent (v/v) glycerol buffered at pH 7·0 with 1/50 *M* phosphate were either oxidized with potassium ferricyanide (2·5 m*M*) or reduced with sodium sulphoxylate (in excess) and examined in the liquid state (23° C.) and after cooling to − 196° C. in liquid nitrogen in a flattened 'Pyrex' tube (light path approximately 5 mm.). The higher concentration of the Boehringer cytochrome *c* was necessary in order to reach the same degree of absorption (O.D. 0·4) as the Sigma preparation at 550 mμ. 70 per cent glycerol proved to be more satisfactory than the 50 per cent used by Keilin and Hartree for observation of the absorption lines. The observations were made with a Zeiss Mikro-Specktralokular (Abbe) using a carbon arc lamp (Phywe 8150) as the source of light, and placing the cytochrome preparation above the microscope condenser. With the vitrified material the observations were completed within 30 sec. after removal from the liquid nitrogen. The spectroscope scale was standardized against the mercury line at 546 mμ. Both commercial preparations of cytochrome *c* showed exactly the same extinction bands, and the results in Table 1 therefore apply to both.

Table 1

| Bands | Absorption lines in the visible spectrum for commercial cytochrome *c* | | | |
|---|---|---|---|---|
| | Reduced | | Oxidized | |
| | Liquid (23° C.) | Vitreous (−196° C.) | Liquid (23° C.) | Vitreous (−196° C.) |
| | 509 mμ | 500 mμ<br>508 ,,<br>511 ,, | very weak, darkening between 520 and 545 mμ and also between 560 and 565 mμ | very weak, darkening between 525 and 538 mμ and also between 560 and 565 mμ |
| β | 522 mμ<br>528 ,, | 517 mμ<br>519 ,,<br>523 ,,<br>528 ,, | | |
| | 540 mμ | 538 mμ | | |
| α | 545–552 mμ | 544 mμ<br>549 ,, | | |

In the reduced state, even at room temperature, very faint bands appeared at 509, 528 and 540 mμ in addition to the usual intense α- and β-bands. Observed in the Beckman *DU* spectrophotometer, these three weak bands appear as shoulders on the absorption curve. Cooling in liquid nitrogen results in striking changes. In addition to a sharpening and intensification of the bands seen at room temperature, a number of new bands appear. There are now very intense and sharp bands at 544 and 549 mμ, fainter but very sharp bands at 508, 517 and 519 mμ, slightly more faint bands at 523, 528 and 538 mμ, and finally two very faint and sharp bands at 500 and 511 mμ. The α-band has been resolved into two bands (544 and 549 mμ) of nearly equal intensity. Maximum intensification of the bands requires about 20 min. immersion in the liquid nitrogen. For unexplained reasons we did not achieve the intensification of the absorption bands by devitrification described by Keilin and Hartree[1]. The same preparation viewed in the glassy state (− 196° C.) with only a tungsten microscope lamp (9 V., 6 amp.) revealed only the 549, 544, 517–19, 528, 523 and 508–11 mμ bands in order of decreasing intensity. A reduced 0·2 per cent (w/v) Sigma cytochrome *c* solution containing

1/15 *M* phosphate, *p*H 7·0, and observed with the same lamp at 23° C. showed absorption bands at 544–552, 519, 528, 509 and 540 mμ.

We are not in a position to say whether these extra bands belong to cytochrome *c* itself, or to partial degradation products of cytochrome *c* [2], or whether they result from the presence of other cytochromes in the preparation. In any event, to our knowledge, these accessory bands have not been previously reported.

The Sigma cytochrome *c* reduced with hydrogen plus palladium–asbestos according to the method of Smith[4] became autoxidized with a first-order rate constant of $3 \times 10^{-3}$ min.$^{-1}$ (*p*H 7·0, 1/15 phosphate, 22° C., $pO_2$ equal to 0·2 atm., measured as decrease in optical density at 550 mμ).

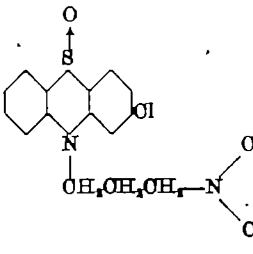
# Identification and Pharmacological Properties of a Major Metabolite of Chlorpromazine

CHLORPROMAZINE is widely used in the treatment of mental illness, but little is known about its metabolic fate. This communication describes the discovery in the urine of dog and man of the sulphoxide derivative and some preliminary studies of its pharmacological properties.

The metabolite was extracted from alkaline urine with ether, separated from chlorpromazine by counter-current distribution, and isolated as the picrate. The empirical formula of the metabolite differed from that of chlorpromazine by one additional oxygen atom. The ultra-violet absorption spectrum of the hydrochloride showed a series of peaks similar to those reported for the sulphoxide of phenothiazine[1]. Identification of the urinary product as the sulphoxide of chlorpromazine:



was established by comparison with the synthetic product. Identity was shown by melting point (207–209° C.) and mixed melting point determination of picrates, and by comparison of ultra-violet and infra-red absorption spectra. Sulphoxide formation is an unusual type of drug bio-transformation, and so far as we know has not been reported; furthermore, the sulphur atom in the metabolite represents a centre of asymmetry[2].

The urinary excretion of chlorpromazine and its metabolite were measured by ultra-violet spectro-

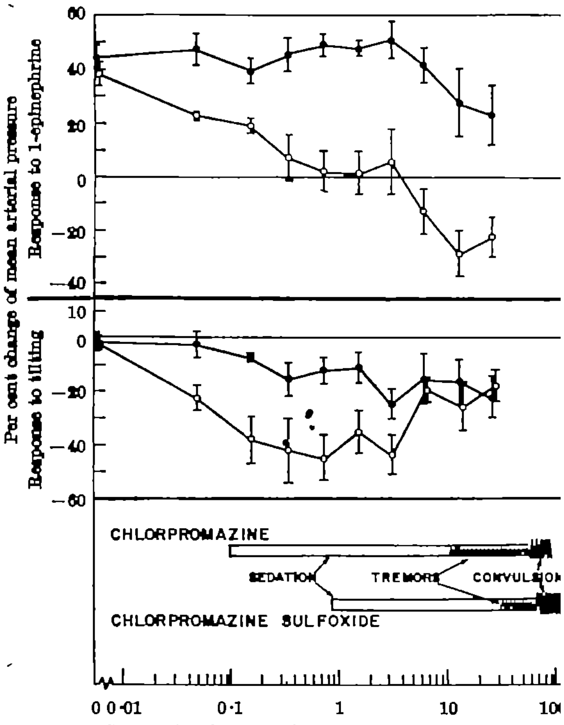


Fig. 1. Effects of chlorpromazine and chlorpromazine sulphoxid on unanaesthetized dogs. Each point represents mean respons of four dogs with standard error of the mean depicted by vertica bars. Open circles, chlorpromazine; closed circles, chlorpromazin sulphoxide

photometry (Salzman, N. P., Greenberg, B., a
Brodie, B. B., unpublished work). Following t
intravenous injection of chlorpromazine (20 mgn
kgm.) into dogs, about 1 per cent was excret
unchanged and about 12 per cent as the sulphoxic
The sulphoxide was also shown to be extensive
metabolized *in vivo*; thus, following administrati
of the metabolite, only about 20 per cent appear
in the urine unchanged. It is probable, therefo
that sulphoxide formation represents a major pat
way of chlorpromazine metabolism. Studies wi
patients receiving chlorpromazine indicated th
significant quantities of sulphoxide, but little or
chlorpromazine, were excreted in urine.

Pharmacological actions of chlorpromazine and
sulphoxide were compared in dogs. The compoun
were given intravenously in geometrically increasi
doses at 15-min. intervals, and vasomotor respons
to adrenalin and to tilting recorded. The compoun
were qualitatively similar, producing sedation, relax
tion of the nictitating membrane, adrenergic bloc
ade, orthostatic hypotension, excitement, tremo
and finally clonic and tonic convulsions. The do
response relationships are illustrated in Fig. 1. T
dose of sulphoxide which produced minimal sedati
was about eight times that of chlorpromazine, b
the sulphoxide caused relatively little adrener
blockade and postural hypotension at sedative dos
Because of the difficulty in evaluating sedati
quantitatively, the values given in Fig. 1 for t
minimal sedative doses are only approximate, wi
no attempt to measure the degree of sedation.

Since chlorpromazine potentiates barbiturates
a central action[3], the effectiveness of the two co
pounds in potentiating hexobarbitone anaesthe

s compared. Dogs were anæsthetized with hexo- -bitone and on awakening were given chlorprom- -ne or the sulphoxide intravenously. Resumption anæsthesia, indicating potentiation, was observed th both compounds, the sulphoxide being about -eighth as active as chlorpromazine. In contrast its activity in dogs, the sulphoxide produced only nimal sedation and potentiation of hexobarbitone mice, rats and rabbits.

Since chlorpromazine sulphoxide induces sedation dogs with relatively little of the orthostatic hypo- sion observed with chlorpromazine, it is planned test the drug in man in the treatment of mental ness.

We wish to thank Dr. Glenn Ullyot, of the Smith, 'ine and French Laboratories, for supplying lorpromazine sulphoxide.

## Function of Heparin

BOTH heparin[1] and histamine[2] are now known to concentrated in the tissue mast cells, and it might us be expected that the release of histamine caused damage to the mast cells would be accompanied the release of heparin and a consequent increase the clotting time of blood. So far this dual effect s been observed in only one species, the dog, in ich an intravenous injection of peptone or of a emical histamine liberator such as compound /80 can release sufficient heparin to render the ood incoagulable. In the rat, however, although mpound 48/80 releases histamine from the numerous ast cells in the subcutaneous connective tissue, the otting time of the rat's blood remains unchanged. e have therefore attempted to discover what ppens to the heparin in the rat following a maximal lease of histamine by compound 48/80.

Two groups of eight female Wistar rats, of 200– 0 gm., were used. The first received intra- ritoneally over a period of five days progressively creasing doses of compound 48/80 in saline, by ich time 1 mgm. per 100 gm. body-weight could given without eliciting signs of shock. The second oup was given equivalent volumes of saline intra- ritoneally as a control. Whole blood-clotting times re measured repeatedly by the capillary tube ethod, and samples of urine, collected on filter per, were tested for metachromatism with a weak lution of toluidine blue. At the end of five days, e two groups were killed and skinned, and as much bcutaneous connective tissue as possible was raped off. Representative tissue spreads were amined histologically for mast cells, the remaining bcutaneous tissue (about 60 gm.) in each group ing then pooled and assayed for histamine and parin as previously described[3], except that on this occasion we used the thiocyanate method[4] for the initial extraction before finally purifying the heparin by the method of Charles and Scott[5].

Compound 48/80 in the dosage used produced widespread degranulation and disruption of the mast cells in the subcutis of rats, and almost complete loss of its tissue histamine—a drop from 26 to 1·5 μgm./gm. tissue (94 per cent loss). On the other hand, the total heparin content fell only from 10·0 to 4·7 I.U./gm. (53 per cent loss), and even this loss was unaccompanied by any sign of the release of heparin into the circulating blood; the clotting time remained normal and no metachromatic material appeared in the urine. That the heparin extracted from the control series did in fact possess anticoagulant activity was confirmed by its action on normal rat blood *in vivo* and *in vitro*.

Thus the almost complete release of histamine from the subcutis of the rat by compound 48/80 is accompanied by a loss of only half the associated heparin. Some of the metachromatic material from the disrupted mast cells may be disposed of locally by macrophages[6,7], some may adhere to adjacent connective tissue fibrils[8] or cells[9], while some may be bound by the basic histamine-liberator itself[10]. Although these same basic compounds can release active heparin into the blood stream of the dog[11], they fail to do so in the rat; the rabbit and the guinea pig appear to be similar to the rat in this respect[12]. This suggests that the function of heparin may be concerned rather with events in the tissues than with the coagulability of the circulating blood.

## Inactivation of Phenyl Mercuric Acetate in Groundwood Pulp by a Mercury-resistant Strain of *Penicillium roqueforti* Thom

AN investigation was started in December 1954 into the storage qualities of groundwood pulp impregnated with 25–35 p.p.m. of phenyl mercuric acetate, compared with unimpregnated pulp made at the same time. One object of this work was to follow the course of infection of the pulps by blueing and wood-rotting fungi (Basidiomycetes), the latter frequently being responsible for the condition known as 'red-rot', and also to try to discover why phenyl mercuric acetate, although toxic to many Basidiomycetes at low concentrations, frequently fails to protect groundwood pulp from attack by 'red-rot' after a few months storage. Some significant conclusions have now been reached.

Phenyl mercuric acetate is highly toxic to many fungi at 2–10 p.p.m. mercury, but it has been known[1,2] for some years that a strain of *Penicillium roqueforti* Thom can tolerate very much higher concentrations. This mould commonly stains mercury-treated pulp quite badly, but it is not cellulolytic. It is mainly infection by Basidiomycetes that causes pulp to deteriorate.

We have shown experimentally that *P. roqueforti* isolated from pulp impregnated with phenyl mercuric acetate can absorb mercury into its mycelium. The mould was grown on liquid media containing 20 p.p.m. of phenyl mercuric acetate. After a month, the mycelium was filtered off, washed and analysed for mercury. About 75 per cent of the weight of mercury found on analysis was present in the fungal pellicle. This suggested that the mould might be able to prevent this fungicide from behaving as a thiol reactor towards more harmful fungi known to be very susceptible to phenyl mercuric acetate *in vitro*.

Monthly examination of bales of both untreated and mercury-treated pulp (manufactured in December 1954) showed that *P. roqueforti* stains first appeared in the treated pulp about eight weeks after manufacture. We have very seldom isolated this mould from untreated pulp. The stains gradually spread farther into the bales month by month; but, unlike the unprotected bales, no evidence of 'red-rot' attack was then apparent. Five months after manufacture, the untreated bales were badly rotted, and the treated bales were extensively stained by *P. roqueforti*. One impregnated bale examined contained a few consecutive sheets having, in addition to the *Penicillium* stains, a small brown stain at one edge, typical of a Basidiomycete. Attempts to isolate the causal fungus failed at this stage.

A suitable bio-assay technique had meanwhile been found for determining the amount of biologically active mercury present in groundwood pulp. Chemical analysis showed that the normal concentration of 25–35 p.p.m. of mercury was present in the pulp sheets; but bio-assay tests showed that the concentration of biologically active mercury fell from 12–13 p.p.m. mercury in the unstained central areas, to 3·4 p.p.m. one inch beyond the border of the *P. roqueforti* stains, and was zero in the stains themselves. The difference in concentration of bio-active mercury compared with total added mercury in the uninfected areas of the sheet is presumably due mainly to partial inactivation by some natural constituents of the pulp. In no case has any biologically active mercury been found in *P. roqueforti*-stained regions of impregnated groundwood pulp containing 25–35 p.p.m. mercury.

Six months from the date of manufacture, the outer regions of the treated bales were quite badly infected by 'red-rot', and *Stereum sanguinolentum* was isolated on a specially developed selective medium which is designed to inhibit fast-growing contaminating moulds, such as *Trichoderma viride*, without affecting the growth of Basidiomycetes.

After seven months, 'red-rot' due to *Stereum sanguinolentum* was well established, and no bio-active mercury was detectable anywhere in the infected sheets. The normal content of mercury w found by chemical analysis.

The evidence obtained shows that: (*a*) the str of *P. roqueforti* Thom normally present in mercu treated pulp is able to absorb a relatively la amount of mercury from nutrient media containi phenyl mercuric acetate; (*b*) progressive infecti of groundwood pulp by this mould reduces c currently the concentration of biologically acti mercury to nil in the stained areas, without affecti the concentration of mercury determinable by che ical analysis; and (*c*) the loss of biologically acti mercury in the pulp studied was followed by seconda infection by *Stereum sanguinolentum*, which cause typical 'red-rot'. It is therefore suggested that *roqueforti* Thom is able to render phenyl mercu acetate inactive as a fungicide, and hence reduce value as a pulp preservative against seconda infection by wood-rotting fungi.

It follows that more efficient protection agai rot should be conferred by using either a no mercurial toxicant, or a mixed toxicant containi a non-mercurial, to which *P. roqueforti* is susceptil at concentrations lethal to Basidiomycetes. Succe ful treatment on these lines has already been reporte

## Use of the Glees Silver Technique in th Hypothalamus

ONE of the most important advances in technic procedures for determining the course and distrib tion of fibre tracts in the central nervous system the method based on the recognition of termin degeneration by silver impregnation. As the autho of these methods have emphasized, however, th need to be used with care and discrimination in ord to avoid possible fallacies of interpretation. We ha recently observed that in certain (but not all) of t cell groups of the hypothalamus and preoptic regi in a number of normal brains (human and macaq monkey) stained by the Glees technique, the appe ance of apparently typical terminal degeneration present. This is particularly the case with the dor medial and ventromedial hypothalamic nuclei. T reason why these nuclei should show this appe ance of 'degeneration' is not clear; but it may related to the peculiar metabolic activities which a known to modify the appearance of axons in so of the hypothalamic nuclei. This observation is importance since it is probable that some investigat have, in the past, mistaken this appearance seen sections of normal brains for true terminal degene tion, and on this basis have described fibre co nexions with widely different parts of the brain.

## Blocking of Lead Tetraacetate–Schiff actions in Tissue Sections by Boric Acid

CURRENT histochemical techniques for carbohydrates depend on the fact that many of these subnces possess groupings capable of being oxidized yield aldehyde residues, which can then be made ible with Schiff's reagent. Glegg, Clermont and blond[1] showed that when lead tetraacetate (in cial acetic acid) replaced periodic acid as the oxiant, the histological distribution of the reaction th Schiff's reagent was similar although the ensity at some sites differed. If this difference in intensity of the Schiff reactions were due to ferential oxidation of *cis* α-glycol groupings by d tetraacetate[2], then boric acid, which readily mplexes with *cis*-hydroxyl groups (for example, in rbohydrates)[3], might be expected to block the idation of such groups and thus modify the bsequent Schiff reaction.

Sections of mouse tissues were treated with a er cent w/v solution of lead tetraacetate (L. Light and Co.) in glacial acetic acid containing 0·1–0·001 *M* boric acid. Controls were processed without boric acid. The presence of boric acid reduced or completely prevented the subsequent reaction with Schiff's reagent only in certain structures, for example, mucus-secreting cells (Figs. 1 and 2). This effect was better demonstrated with ethanolic Schiff's reagent[4]. If sections were successively treated with boric acid in glacial acetic acid and lead tetraacetate, the Schiff reaction was not blocked, nor was the effect of a solution containing both reagents enhanced.

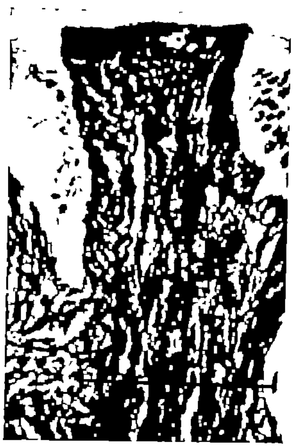

Fig. 3. Gingiva from a patient with phenytoin sodium gingival hyperplasia, stained by Gomori's method, showing collagenous and reticular fibres in the lamina propria between two epithelial ridges

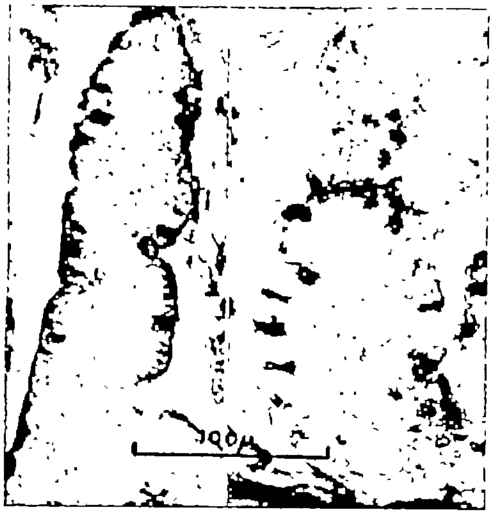
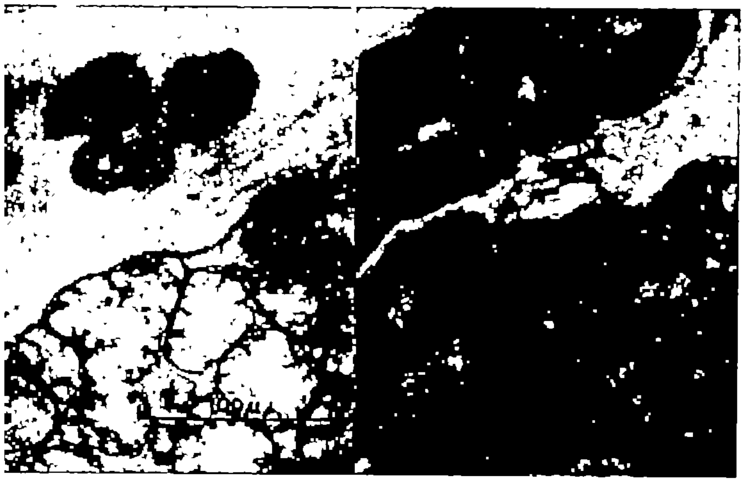


(a) (b)

'ig. 1. Goblet cells of small intestine, in ethanolic Schiff's eagent after 4 hr. at 23° C. 1 per cent lead tetraacetate; (a) containing 0·01 *M* boric acid, (b) without boric acid

'Model' experiments with galactogen[5] and glycogen (Kahlbaum) incorporated in gelatin films have shown that, histochemically as well as chemically[2], lead tetraacetate oxidizes adjacent *cis*-hydroxyl groups more rapidly than adjacent *trans*-hydroxyl groups: and that boric acid modifies the subsequent Schiff reaction, probably by forming oxidation-resistant complexes with adjacent *cis*-hydroxyl groups of carbohydrates. Since these groups are present in several animal glycoproteins[6], these results may also apply to the tissue sections.



(a) (b)

Fig. 2. Mucous glands of larynx, in ethanolic Schiff's reagent, as in Fig. 1

Sections of a gingival biopsy from a case of phenytoin sodium gingival hyperplasia (Fig. 3), in which there is increased production of collagen[7], were placed in a 0·8 per cent w/v solution of pectinase (L. Light and Co.), *p*H 4·2, for 21½ hr. at room temperature; after washing, they were treated first with lead tetraacetate solution and then with aqueous Schiff's reagent. The action of the pectinase was similar to that reported for dermis[8]; but it was found that with boric acid present in the lead tetraacetate solution, little or no staining took place. This suggests that 'pectinase' releases the α *cis*-hydroxyl structure from collagenous and reticular fibres, presumably from carbohydrate components[8,9], and also illustrates a possible application of the boric acid blocking technique in studies on enzymes of unknown specificity acting on complex substrates.

Further work is in progress, and will be reported elsewhere. I wish to thank Dr. D. J. Bell for a specimen of galactogen, and Dr. L. N. Owen for advice and encouragement.

## Role of Glutamine in Urea Synthesis

In 1939, it was suggested by one of us[1] that the amide-nitrogen of glutamine was a source of urea-nitrogen and that urea formation was paralleled by a continuous re-synthesis of glutamine. Evidence has now been obtained for a reaction between bicarbonate (as the source of urea-carbon) and the two nitrogenous groups of glutamine. This appears to represent the first of the sequence of reactions leading to urea synthesis. The evidence for this step is based on the observation that when liver slices are incubated with glutamine in absence of added bicarbonate, not only was urea synthesis practically suppressed but also neither the glutamine-amide-nitrogen nor the amino-nitrogen of glutamine was utilized to any extent. On the other hand, in the presence of bicarbonate a considerable synthesis of urea occurred with the simultaneous utilization of amide-nitrogen and of amino-nitrogen (Table 1). The small quantities of ammonia derived from glutamine and formed during the incubation were unaffected by bicarbonate and therefore appear to be unrelated to urea synthesis. That glutamine rather than ammonia or ammonium glutamate acted as a direct source of urea-nitrogen was demonstrated in several ways: first, by the fact that the rate of urea synthesis from glutamine was directly proportional to the substrate concentration, whereas this was not so when ammonia served as a substrate (Fig. 1). A slight inhibitory effect of ammonia was observed at the highest concentrations tested. Secondly, inhibition of glutaminase by sulphophthaleins had no effect on the synthesis, whereas activation of glutaminase with pyruvate almost completely inhibited urea formation. Finally, evidence was obtained by paper chromatography for a considerable formation of glutamine from ammonium salts in liver slices. These observations provide evidence for the role of glutamine, as distinct from ammonium glutamate, in urea synthesis and suggest that urea formation from ammor may depend upon a transitory formation glutamine.

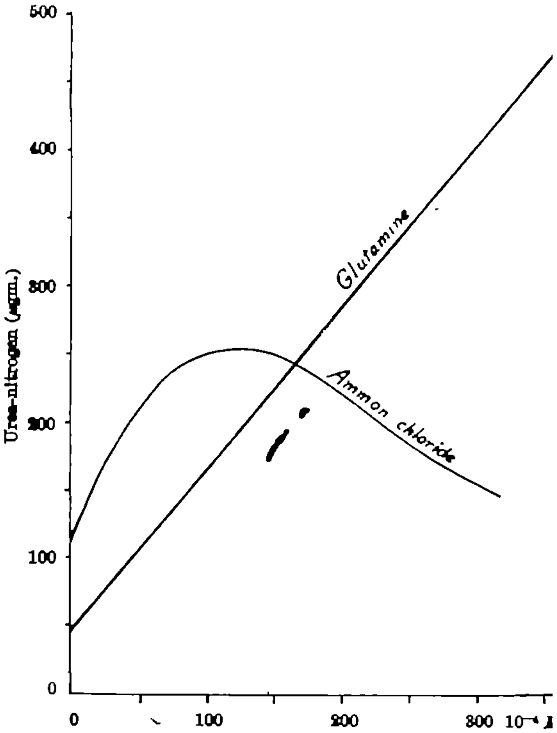

Fig. 1. Urea synthesis from glutamine and ammonium chlorid in rat liver slices; incubation time 90 min. at 37°; 200 mgm slices in bicarbonate Ringer. The positions of the lines on th graph were calculated from the results of approximately 20 experiments

Attempts to replace glutamine in urea synthe by other amides such as asparagine, glycineamide oxamide were unsuccessful. However, prelimina experiments with *iso*glutamine (II) showed a gre superiority of this compound over glutamine, phenomenon which may be significant for the int pretation of the synthesizing mechanism discuss below.

Table 1. Effect of Bicarbonate on the Utilization of Glutam Nitrogen for Urea Synthesis

200 mgm. liver slices incubated with glutamine (0·02 *M*) in 4 Ringer solution buffered at pH 7·4

| | Utilization of glutamine | | Formation of | |
|---|---|---|---|---|
| | Amide-nitrogen (μgm.) | Amino-nitrogen (μgm.) | Ammonia-nitrogen (μgm.) | Urea-nitroge (μgm |
| With bicarbonate | 170 | 145 | 37 | 287 |
| Without bicarbonate | 66 | 25 | 36 | 34 |

Table 2. Contribution of Glutamine-Nitrogen to Ur Nitrogen

Figures represent averages of eight experiments: conditions as Table 1

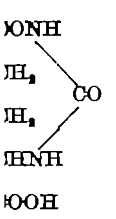
| Contribution from: | | | Formatio of urea-nitrogen |
|---|---|---|---|
| Amide-nitrogen | Amino-nitrogen | Total glutamine-nitrogen* | |
| 166 μgm. | 156 μgm. | 281 μgm. | 264 μgm. |

* Corrected for small quantities of ammonia-nitrogen libera during incubation

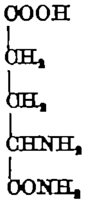
In a further series of experiments, the urea formed ɔm glutamine and bicarbonate in liver slices, was timated side by side with the disappearance of cide-nitrogen and amino-nitrogen. These balance periments (Table 2) showed that the contribution amide-nitrogen to urea-nitrogen approximately [ualled that of the amino-nitrogen. They further vealed that the sum of the contributions of amide- trogen and amino-nitrogen, corrected for the small antities of free ammonia formed during the incuba- on, was of the same order as the total urea-nitrogen nthesized. It is therefore concluded that the follow- g equation represents the overall synthesizing echanism :

glutamine-amide-nitrogen + 1 glutamine-amino-nitrogen = 2 urea-nitrogens

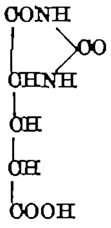
Experiments with sodium bicarbonate($^{14}C$) and ith other monocarbon compounds confirmed the iginal view of Krebs and Henseleit[2] that bicarbonate the principal, if not the only source of carbon for ea. Thus, as described above, it is bicarbonate or derivative which reacts initially with the nitrogenous oups of glutamine. Whether this reaction is directly ıked with the ornithine cycle of Krebs and Henseleit[2] as not investigated in this work.



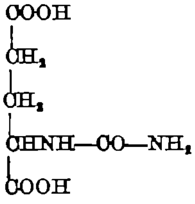
(I)



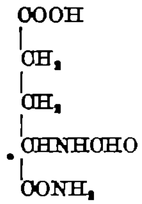
(II)



(III)

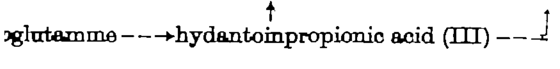


(IV)



(V)

As a result of the initial reaction, the formation a ureido-compound of type (I) could be envisaged. owever, in view of the strong effect of *iso*glutamine ı urea synthesis, it is also possible that *iso*glutamine ther than glutamine may act as the principal source nitrogen. In this case the subsequent formation hydantoinpropionic acid (III) could be postulated. hydrolytic split of the amide-nitrogen linkage or ı oxidative split of the amino-nitrogen linkage the compounds (I) and (III) would lead to the rmation of carbamyl derivatives. If the hydrolytic ılit occurred first, N-carbamylglutamic acid (IV) ould arise from either compound, an intermediary hich has been reported to act as a catalyst in urea nthesis[3].



The transitory formation of hydantoinpropionic acid (III) from *iso*glutamine (II) in urea synthesis is particularly worthy of consideration, since it has been claimed that these two compounds as well as the closely related formyl*iso*glutamine (V) occur as intermediates during the degradation of histidine[4], which is one of the strongest urea-synthesizing amino-acids[5].

A detailed account of this work will appear elsewhere.

## Hæmagglutinins of *Glycine soja*

The hæmagglutinins of *Glycine soja* (synonyms: *Glycine max*, *Soja hispida*, *Dolichos soja*, *Soja angustifolia*), stated to be inactive against human erythrocytes but active against certain animal cells, particularly those of the rabbit[1], have been found to agglutinate human red blood corpuscles non-specifically in the cold[2].

I observed[3] that when extracts of the seeds of *Glycine soja* (var. Bansei) were absorbed in the cold with human erythrocytes of group *O*, until they were no longer agglutinated, the extract could still agglutinate *A* and *B* cells, not only in the cold, but also at 37° C. Subsequent absorption with corpuscles of group *A* left residual activity for those of group *B*. The anti-*O* component of these extracts appeared to suppress the activity of the anti-*A* and anti-*B* components.

Further studies of *Glycine soja* extracts have now been conducted which have shown that the extracts contain incomplete agglutinins for human red blood corpuscles, since albumin suspensions of human erythrocytes and papainized human red cells are agglutinated non-specifically at laboratory temperatures and at 37° C.

*Glycine soja* therefore appears to contain: (i) agglutinins acting powerfully, even at 37° C., on rabbit erythrocytes suspended in saline; (ii) non-specific cold agglutinins for human erythrocytes suspended in saline; (iii) incomplete agglutinins for human erythrocytes, acting both in the cold as well as at higher temperatures.

Absorption and elution experiments, to be described elsewhere, have shown that the same agglutinins are responsible for the diverse serological reactions indicated above.

It appears that the thermal amplitude of *Glycine soja* agglutination is not entirely a property of the agglutinins, because the same agglutinins have widely differing thermal amplitudes for human and rabbit erythrocytes. It appears that cell receptors play a part in determining the thermal amplitude of *Glycine soja* agglutination.

It is conceivable that a mixture of complete cold agglutinins and incomplete warm agglutinins can give rise to the suppression phenomenon[3]. However, as the cold agglutinins and the incomplete agglutinins appear to be identical, the mystery of the separability of component agglutinins for *O*, *A* and *B* erythrocytes and the increased thermal amplitude after absorption with red corpuscles of group *O* remains to be solved.

## Production of Diphtheria Toxin in Submerged Culture

WE have shown[1] that diphtheria toxin with a value of 150–200 flocculating units per ml. can be obtained by growing the Park–Williams No. 8 strain of *C. diphtheriae* as a submerged culture, using a tryptic digest medium based on that described elsewhere[2]. The volumes employed were 10–14 litres of medium, and the vessels were of glass, with stirrers made of either 'Birmabright' (a magnesium–aluminium alloy) or aluminium.

In recent developments of this technique, we have used 80-litre tanks, made from commercial aluminium, which offer many advantages over glass vessels for routine toxin production. They permit of a much better control of temperature during the growth of *C. diphtheriae* and are more suitable for sterilization of the culture medium. Vortex stirring[3] has been used, and sterile air at a rate of 0·05–0·15 litre per min. per litre of culture medium has been found satisfactory.

The time required for maximal toxin production has been found to be very dependent on the size of the initial inoculum employed. For routine toxin production a growth period of the order of 48 hr. is very convenient, and for this an initial inoculum of 200 ml. of a 48-hr. shaken culture of *C. diphtheriae* for a volume of 50–60 litres of medium has been found satisfactory. If a much larger inoculum is used, for example, 10 litres of 24-hr. culture produced in a small seed-tank, peak toxin production is obtained in about 28 hr.

As an alternative method, we have withdrawn approximately half the culture when the peak toxin value has been reached and replaced it with an equal volume of fresh sterile medium. After this replacement, the toxin production is a maximum in 24 hr., and this procedure may be repeated many times, thus giving in effect a semi-continuous daily toxin production of 30 litres per tank. Unfortunately, the initial purity of the toxin, which is of the order of 1,500 Lf. units per mgm. protein nitrogen, is not maintained, and for this reason we prefer to harvest single batches of toxin rather than to run a semi-continuous process. An example of a result obtained in this way is shown in Table 1.

With the equipment and methods now in use, we have been able to produce large volumes of culture filtrates from *C. diphtheriae* having an Lf. value of the order of 180–250 units per ml. The advantages of submerged culture methods over the older surface-culture technique are very obvious. Toxin production in shallow layers of culture medium necessitates the manipulation and inoculation of hundreds of bottles —a laborious process where comparatively lar amounts of culture filtrate are required. By th submerged culture method, however, large volum of medium can be handled with ease and it is possibl for example, to take uniform samples at frequen intervals (for example, 2-hourly) throughout th growth period so that determinations of total growt toxin production, and metabolic changes may b studied. Observations on these points and oth factors which influence toxin production will b reported later.

Table 1. SUBMERGED CULTURE NO. 187
Aluminium tank with vortex stirrer, capacity 80 litres. Cult medium. 50 litres of tryptic digest medium. Inoculum: 10 lit of a 24-hr. growth of *C. diphtheriae* prepared in a small submerg culture tank. Air flow: 6 litres per min. across the surface. Te perature: 35° C

| Growth time (hr.) | *p*H | Lf (U./ml.) | Protein nitrogen (mgm./ml.) | Purity (Lf./mgm. pro tein nitrogen) |
|---|---|---|---|---|

* Initial values after inoculation

† At 28 hr., 35 litres of culture were removed and replaced 30 litres of sterile culture medium.

Previously[1], we stated that vessels made fro commercial aluminium showed signs of attack o continued use, accompanied by a decrease in tox production. The vessels now in use (of modifie design) have not shown this attack, and there ha been no decrease in toxin production on continue usage. Possibly a difference in composition of th aluminium used for the first experimental tan accounted for this finding.

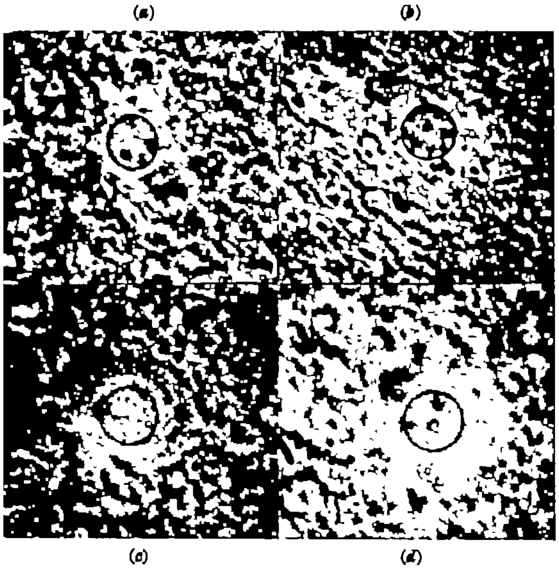
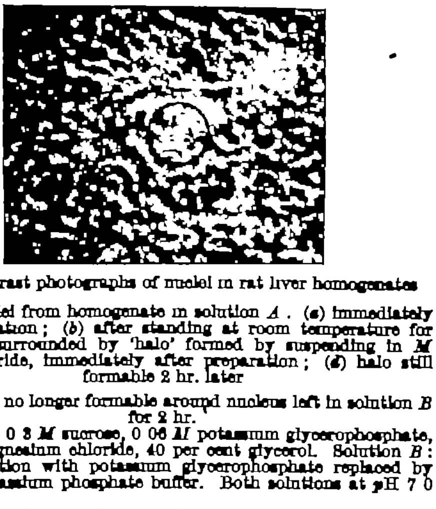
## Preservation of Rat Liver Nuclei by Potassium Glycerophosphate

Appelmans and de Duve[1] found that the 'osmoti activation' or lysis undergone by rat liver mitc chondria in hypotonic media could be prevented b the presence in the medium of 0·25 *M* sucrose; th sucrose could be partly replaced by an iso-osmola quantity of β-glycerophosphate. They showed tha mitochondria released certain enzymes as a resul of osmotic activation. If deoxyribonuclease, whic





Phase-contrast photographs of nuclei in rat liver homogenates

Fig. 1. Nuclei from homogenate in solution *A*. (*a*) Immediately after preparation; (*b*) after standing at room temperature for 2 hr.; (*c*) surrounded by 'halo' formed by suspending in *M* sodium chloride, immediately after preparation; (*d*) halo still formable 2 hr. later

Fig. 2. Halo no longer formable around nucleus left in solution *B* for 2 hr.

Solution *A*: 0·3 *M* sucrose, 0·06 *M* potassium glycerophosphate, 0·001 *M* magnesium chloride, 40 per cent glycerol. Solution *B*: Control solution with potassium glycerophosphate replaced by 0·005 *M* potassium phosphate buffer. Both solutions at *p*H 7·0

chneider and Hogeboom[2] have shown to be largely ssociated in liver with mitochondria, is also released y osmotic activation, this might explain the effectiveess of sucrose in media for the isolation and preservaion of nuclei. Anderson[3] has shown that sucrose revents 'bleb' or bubble formation on the nuclear urface, and that bleb formation occurs on nuclei reated with deoxyribonuclease.

We have tested the effectiveness of potassium -glycerophosphate as a complete or partial subtitute for 0·3 *M* sucrose in preserving nuclei in the resence of mitochondria. The criteria used were: a) preservation of the original degree of contrast f the nuclei under the phase-contrast microscope, nd (*b*) formation of 'haloes' (Fig. 1,*c*) around the uclei when suspended in *M* sodium chloride, inicating that deoxyribonucleic acid was still present n a form that is extractable and sufficiently iscous to push the mitochondria away from the ucleus. The other components of the medium were 0 per cent glycerol, 0·001 *M* magnesium chloride, nd 0·005 *M* potassium phosphate buffer *p*H 7·0, here there was no glycerophosphate present for H buffering. Under these conditions, 0·16 *M* otassium glycerophosphate was more effective than ·3 *M* sucrose for preserving nuclei; but it caused them to clump, probably through partial dissociation of nucleohistone. 0·12 *M* and 0·09 *M* were also more effective than sucrose, the higher concentration being better than the lower; their effectiveness was independent of whether sucrose was also present. 0·06 *M* glycerophosphate was effective only if 0·2 *M* sucrose or more was also present, so at this level the effects seem to be additive.

The best combination (solution *A*) appeared to be 0·3 *M* sucrose + 0·06 *M* potassium glycerophosphate, plus the other components mentioned above (Figs. 1,*a* and *b*). When this mixture was used, viscous deoxyribonuclease was still extractable after leaving nuclei in the presence of mitochondria at room temperature for periods up to 24 hr. (Figs. 1,*c* and *d*). Fig. 2 shows that this was not the case when glycerophosphate was replaced by 0·005 *M* potassium phosphate buffer (solution *B*). It is not clear why potassium glycerophosphate should be more effective than sucrose; but the results fit in with de Duve's findings, and suggest that the protective action of both substances on nuclei may be due to their prevention of the liberation of deoxyribonuclease from mitochondria. With all mixtures used, the fewer mitochondria there were present, the longer the nuclei were preserved.

# Inability of Varied-Carpet Beetle Larvæ (*Anthrenus verbasci* L.) to digest Chitin

A few animals are known to possess in their digestive juices a chitinase enabling them to digest chitin. The occurrence of a chitinase in the gut of the snail (*Helix pomatia* L.) was demonstrated long ago[1]. A similar enzyme is present in the intestinal tract of different earthworms[2], eelworms[3], snails and slugs[4], and in the terrestrial isopod *Porcellio scaber* Latr.[5]. Among the snails, and probably also other terrestrial pulmonate gastropods, the intestinal chitinase is not produced by the glands of the animal, but appears to be of microbial origin[4].

It is often thought by entomologists that pests of collection specimens digest chitin and live on a diet containing a high percentage of chitin. However, it has never been demonstrated that this chitin is actually utilized. The following investigations were carried out using varied-carpet beetle larvæ (*Anthrenus verbasci* L.) (Coleoptera, Dermestidae), in order to check their view.

(1) *Absence of chitinase in glycerol extracts of digestive tracts.* Larvæ of *A. verbasci* were reared on dried insects. Fully grown larvæ (about 5 mm. long) were cleaned and carefully dissected under a binocular microscope. Sixty-four isolated digestive tracts were ground in a small mortar with 5 ml. of 5 per cent glycerol and clean sand, at 0° C. After centrifugation, the chitinolytic activity of the clear supernatant fluid was tested, using both nephelometric and chemical methods previously described[4].

After 22 and 72 hr. of incubation, at $pH$ 6·5 and 36° C., under aseptic conditions, no chitinolytic activity could be detected.

(2) *Absence of chitinolytic bacteria in the digestive tract.* Four larvæ, grown on dried insects, were cleaned and aseptically dissected in a sterile chamber. The digestive tracts were ground in a sterile mortar and suspended in 2 ml. sterile distilled water. 1 mgm. of excreta of larvæ was similarly suspended in 2 ml. distilled water.

The suspensions were then added to a sterile agar–agar medium containing finely powdered chitin, and plated in Petri dishes[6]. After ten days, no chitinolytic bacteria could be detected: no typical clarification of the medium, such as that usually observed with all chitinolytic bacteria of different sources[4,6], was noticed. Digestive tracts and also excreta are particularly poor in micro-organisms, and seem to be entirely devoid of chitinolytic bacteria.

(3) *Chitin balance in the diet of larvæ reared in controlled conditions.* When reared on a diet consisting of dried insects (adults of *Musca* sp., *Palomena prasina* and *Doryphora decemlineata*), larvæ of *A. verbasci* are able to utilize a maximum of 30 per cent (in dry weight) of the available diet. Two sets of experiments were carried out with larvæ reared for three months on a diet of a known content of chitin, at 28° C. and 50 per cent relative humidity. One control experiment consisted of exposing the same food in the same incubator without larvæ.

In one experiment, chitin was estimated by purification of the material, using the method of Black and Schwartz[7], the residue being weighed as pure chitin. The loss of chitin in the food seemed rather important (28 per cent with dried *Musca* and *Palomena* as diet, 8·5 per cent with *Doryphora*). But this method was found afterwards to be quite unsatisfactory in this particular case owing to the fact that purification is not completed (some proteins remain unhydrolysed) and the excreta, being of a very finely powdered material, are not easily retained during manipulations.

In a second experiment, chitin was estimated by purification of the material with 6 per cent potassium hydroxide at 100° C. for 2 hr.; $N$ hydrochloric acid at 20° C. for 2 hr.; again 6 per cent potassium hydroxide at 100° C. for 2 hr.; 1 : 1,000 potassium permanganate at 60° C. for 20 min.; sodium metabisulphite; hot water, alcohol, ether. These different chemical treatments and the washings were performed in centrifuge tubes, the residue being centrifuged after each treatment for a long time, to prevent any loss of small particles. Estimation of chitin in the final residue was by nitrogen determination (Kjeldahl method).

In these conditions, the loss of powdered material was considerably reduced. The difference in chitin-nitrogen between controls and a diet consisting of dried *Palomena prasina* on which fifty larvæ were reared for three months reached 4 per cent only, this value being within the normal limits of error of the method. Thus chitin is not digested and can be nearly completely recovered in a controlled diet, although the cuticles of the dried insects are partially destroyed and reduced to powder by the larvæ.

Hence we conclude that, using an adequate method for the estimation of chitin balance in dried insects eaten by *Anthrenus verbasci* larvæ, no significant loss of chitin could be observed. The digestive tracts of these larvæ are devoid of chitinase and of chitinolytic micro-organisms. Such larvæ are unable to digest chitin, although there is a high content of chitin their usual diet.

## Supra-Sternal Ossicles in Primates other than Man

DR. G. T. ASHLEY's communication[1] prompts me record a further example of supra-sternal ossicles primates, this time in *Perodictious potto*. The spe men, which was the prepared skeleton of a you animal, showed a supra-sternal ossicle on the rig side only, contributing to the articular surfa for the clavicle (Fig. 1). The ossicle on the left si was presumably lost during preparation. From comparison with the adult sternum, it would appe that in *Perodictious* the supra-sternal ossicles a responsible for the prominent antero-lateral angl of the manubrium sterni and thus for the dee supra-sternal notch. It is possible that they are regular feature in the development of the sternu in this animal. It must not be forgotten, howeve that the supra-sternal notch in man is considerabl shallower in the newborn than in the adult, thoug supra-sternal ossicles do not seem to be a consta feature here.

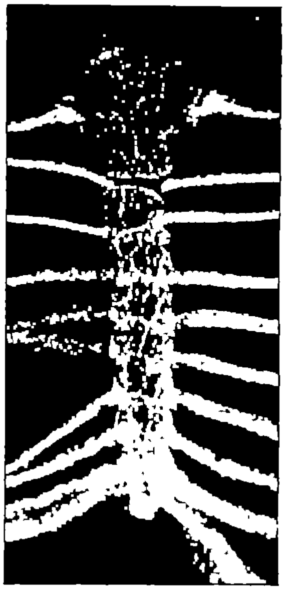

Fig. 1. Radiograph of the sternum of an immature *Perodictious potto* showing the presence of a supra-sternal ossicle on the right side

Society of Chemical Industry, Food Group—Nutrition Panel t the Linnean Society of London, Burlington House, Piccadilly, ondon, W.1), at 6.30 p.m.—Second meeting in the new series Nutrition Requirements and Food Fortification".

British Psychological Society, Medical Section (at the Royal ociety of Medicine, 1 Wimpole Street, London, W.1), at 8.30 p.m.—r. James Laver: "The Psychology of Fashion".

## Thursday, December 15

Society of Chemical Industry, Road and Building Materials roup (in the Lecture Hall of the Junior Institution of Engineers, epys House, 14 Rochester Row, London, S.W.1), at 2.30 p.m. and p.m.—Special meeting on "New and Revised Test Methods".

Institution of Mining and Metallurgy (at the Geological ociety of London, Burlington House, Piccadilly, London, W.1), at p.m.—Scientific Papers.

London Mathematical Society (at the Royal Astronomical ociety, Burlington House, Piccadilly, London, W.1), at 5 p.m.—r. J. C. Shepherdson: "The Factorisation of Polynomials in a inite Number of Steps".

Institution of Civil Engineers (at Great George Street, Westinster, London, S.W.1), at 5.30 p.m.—Sir Richard Southwell, F.R.S.: MacQuorn Rankine and his Work".

Institution of Electrical Engineers, Utilization Section t Savoy Place, London, W.C.2), at 5 30 p.m.—Dr. A. Nemet and r. W. F. Cox: "Intensification of the X-Ray Image in Industrial adiology".

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. R. E. Davies: "Biochemical Aspects of Gastric Secretion". (Last of fifteen lectures on "The Scientific Basis of Medicine".)*

Institution of Mechanical Engineers, Hydraulics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m—Discussion on "Filtration of Liquids".

Oil and Colour Chemists' Association (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p m.—Mr. R. R. Coupe and Mr. A. H. Smith: "Penetration of Ink into Paper and its Relevance to Print Quality".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

## Friday, December 16

Biochemical Society (at St. Thomas's Hospital Medical School, London, S.E.1), at 2 p.m.—Scientific Papers.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4 15 p.m.—Geophysical Discussion—"World-wide Circulation and Exchange of Water". Chairman: Dr. G. E. R. Deacon, F.R.S. Speakers Dr. W. H. Munk, Dr. D. W. Privett, Dr. R. C. Sutcliffe and Mrs. M. Morgan.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. H. A. Watson: "Fuel Control and Burning in Aero-gas-turbine Engines" (James Clayton Lecture).

Royal Aeronautical Society (at 4 Hamilton Place London, W.1), at 7 p.m.—Lord Ventry: "Airships of To-day".

## Friday, December 16—Saturday, December 17

Universities of Great Britain and Northern Ireland (in the William Beveridge Hall, University of London Senate House, London, W.C.1)—Home Universities Conference, 1955.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Demonstrators in the Department of Physics—The Registrar, King's College, Newcastle-upon-Tyne (December 15).

Chemist or Physicist (with a good honours degree in chemistry or physics, and with industrial or commercial experience), to lead a team involved in overseas sales of special atomic energy materials and equipment (Ref. 1,191); Industrial Chemist (with a good honours degree in chemistry or chemical engineering or equivalent qualifications, and several years industrial experience on chemical production, and capable of making critical assessments of essential items of process technology) in the Commercial Section (Ref. 1,192); and a Chemist Engineer (with a good honours degree in chemistry or chemical engineering, and with industrial or research experience), to assist in negotiating for the production and sale of atomic energy materials and equipment (Ref. 1,193)—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, quoting appropriate Ref. No. (December 16).

Physicists (with a university degree or equivalent qualification in physics) in the Central Electricity Authorities' Research Laboratories, Leatherhead, for duties which include research on problems associated with the generation and transmission of electricity—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting NAT/702 (December 16).

Chemist (with a good honours degree or equivalent qualification) for analytical investigational work at the National Coal Board's Coal Survey Laboratory in Chester—Staff Department (Personnel), National Coal Board, Hobart House, Grosvenor Place, London, S.W.1, quoting SS/121 (December 17).

Research Assistant (medically qualified) in Clinical Medicine—The Registrar, The University, Leeds 2 (December 17).

Senior Assistant Physicist (with an honours degree in physics and previous experience in hospital physics)—The Personnel Officer, St. Thomas's Hospital, London, S.E.1 (December 17).

Lecturer (with specialist qualifications in hydraulics) in the Department of Fluid Mechanics—The Registrar, The University, Liverpool (December 19).

Assistant Zoologist (with an honours degree in zoology or specialized in entomology or plant nematology) for work in connexion with the beet eelworm and related species of cyst-forming nematodes—The Secretary, School of Agriculture, The University, Cambridge (December 20).

Lecturer in the Department of Bacteriology—The Secretary, The University, Edinburgh (December 21).

Professor (with high academic qualifications in the field of mathematics and teaching experience of pure and applied mathematics) of Mathematics, at the Royal Naval College, Greenwich, London, S.E.10—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting 4527/55 (December 22).

Electrical or Mechanical Engineer (with a first- or second-class honours degree or equivalent qualification in engineering) at a Ministry of Supply Armament Research and Development Establishment, near Sevenoaks Kent, to conduct a basic development programme in mechanical and electromechanical devices for projectiles and rockets—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.548/5A/CA (December 23).

LECTURER IN PSYCHOLOGY at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 30).

GEOLOGISTS or SENIOR GEOLOGISTS (4) (with a first- or second-class honours degree in geology or equivalent qualification, or high professional attainments) IN THE ATOMIC ENERGY DIVISION of the Geological Survey and Museum, London, S.W.7—Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.168/169/56 (January 4).

LECTURER in either CIVIL ENGINEERING or MECHANICAL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (January 4).

SENIOR RESEARCH OFFICER or RESEARCH OFFICER (with a university honours degree in engineering, physics, textile science or equivalent qualifications, with additional research experience, not necessarily in textiles) IN THE PHYSICS AND ENGINEERING UNIT, Wool Textile Research Laboratory, Commonwealth Scientific and Industrial Research Organization, Sydney, N.S.W., Australia, to undertake research into the mechanical properties of assemblies of fibres with particular reference to the physical basis of chemical treatments to improve crease retention, dimensional stability and shrink resistance of wool products—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (January 6).

ASSISTANT EDUCATIONAL PSYCHOLOGIST—The Director of Education, Shire Hall, Durham (January 7).

CHAIR OF ORGANIC CHEMISTRY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 14).

LECTURER IN PHYSICS at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (January 16).

READER IN BOTANY at Bedford College, Regent's Park, London, N.W.1—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 25).

READER IN ORGANIC CHEMISTRY, and a READER IN PHYSICAL CHEMISTRY, at King's College, Strand, London, W.C.2—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 30).

SENIOR LECTURER and a LECTURER IN VETERINARY PATHOLOGY—The Secretary of University Court, The University, Glasgow (January 31).

LECTURER (honours graduate in physics or chemistry) IN TEXTILE CHEMISTRY—The Registrar, College of Technology, Manchester 1 (February 6).

ASSISTANT CONSERVATORS OF FORESTS (with a university degree in forestry) in Trinidad—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.61/38/01.

BIOCHEMIST (preferably with not less than two years post-graduate research experience either in carbohydrate or protein biochemistry or in endocrinology) to work in the Physiology Department on mammary gland metabolism—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 55/22.

CHEMIST (with at least a second-class honours degree in chemistry, or the A.R.I.C.), in H.M. Overseas Civil Service, Antigua, Leeward Islands, to provide chemical control and advice for the industrial and agricultural development of Antigua—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.63/34/03.

CHEMISTRY MASTER (with an honours degree in chemistry and experience of teaching at G.C.E. or equivalent level), for G.C.E. courses, under the Iraqi Ministry of Education, Baghdad, Iraq—Dr A. H. Hilli, Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7.

GEOLOGISTS (with a university degree in geology), in the Department of Mines, Tasmania, to undertake geological work throughout the State, including investigating and reporting on mines and prospects, general geological work and mapping of areas, advice on water supply, selection of bore sites, and other engineering problems—Agent General for Tasmania, 457 Strand, London, W.C.2.

LECTURER (with an honours degree in metallurgy and preferably with industrial and research experience) IN METALLURGY—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

MICROANALYST (Chief)—Prof. H. A. Brande, Organic Chemistry Laboratories, Imperial College, London, S.W.7.

OPERATIONAL RESEARCH OFFICER (with a good university degree in mathematics, science, engineering or economics, and previous operational research experience), to join a team engaged in the study and development of factors affecting productive efficiency throughout the Corporation—Head Office Personnel Officer, British European Airways, Keyline House, Ruislip, Middx.

PHYSICIST or ELECTRICAL ENGINEER (with at least H.S.C. (science) or equivalent, and experience of electronic equipment) at a Ministry of Supply Armament Research and Development Establishment near Sevenoaks, Kent, for experimental design and development of electronic parts of fuses for projectiles and rockets and associated test and trials equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.538/5A/CH.

RESEARCH ASSISTANT (with H.N.C. or equivalent qualification, and previous experience of chemical analysis) IN THE CHEMISTRY DEPARTMENT, to carry out laboratory experiments connected with the physical chemistry of solid steel—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting O.P.2.

SENIOR EXPERIMENTAL OFFICER (with H.S.C. with mathematics or a science subject as principal subject or equivalent qualifications, and an aptitude for analysis of technical information and in particular numerical data), to supervise a technical office concerned with collection, correlation and presentation of works' performance data; presentation of Group programmes; preparation of Group stock accounts for special materials, and building up of basic operational data—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, quoting 1,196.

# THE WATER PROBLEM IN GREAT BRITAIN

WITH many reservoirs in Britain half empty as a result of the summer drought and its prongation into the autumn, concern is once again eing expressed about the water resources of the untry. It is not easy for the general public to concile restrictions and appeals for constraint with eriods of apparently normal rainfall, and yet this equently occurs. Even to the layman, there is learly something amiss when water conservation rces an interruption of supplies in normally wet ocalities such as Durham. These are but the first ortents of a problem which shows every sign of ecoming more acute with the passage of time.

The total amount of water supplied by water underkings in England and Wales at present is estimated be in the region of 1,750 million gallons a day, or an verage of some 40 gallons per head of the population. his amount has been steadily rising during the past wo decades, and it has been estimated that the water ndertakings will be called upon to supply in fifteen ears time at least twice the amount consumed in 938. This rapidly rising rate of consumption is artly connected with the increased population and s rising standard of living ; but water requirements re increasing much faster than the growth of opulation. Improved sanitation and hygiene and the ift from rural or urban areas account for much ; ut it is the spectacular consumption in the industrial eld which calls for most comment. Increasingly rmidable demands are being made by industry.

For example, it is estimated that the refining of ne barrel of crude oil requires eighteen barrels of ater, the production of a ton of steel needs 65,000 allons of water, a ton of sulphite paper similarly eeds 64,000 gallons, the processing of a gallon of lcohol requires 100 gallons of water ; while the emands of thermal generating stations and atomic ower stations begin to look astronomical—some 80 allons are needed for each kWh. produced. At the me time, numerous industrial establishments disarge waste of many kinds such as acids, oils, chemals, etc., which pollute the streams because of their oisonous, harmful or offensive effect. Cooling water turned to streams at high temperature further omplicates the supply for cities and industries ownstream. The problem is, of course, by no means nfined to Great Britain. Even in the United States e industrial use of water has exceeded the agriultural use, and the Paley Commission has estimated at by 1975 industry will be consuming two-thirds all available sweet water, and that availability of ater will be the main factor in determining the cation of industry.

Agricultural demands in Great Britain may shortly ggravate the problem still further. The possibility controlled growth of crops and grass by summer rigation (already demonstrated by successful experients at Rothamsted Experimental Station) involves cceptional demands for water. In south-east Engnd in a dry summer, up to 250,000 gallons per acre uld be usefully applied.

While Nature is fairly bountiful in her supply of water to the British Isles—it is estimated that in a year of average rainfall some 2,000 gallons of water per head per day descends upon us—the greater part is 'lost' in sustaining river-flows to the sea, and this water returns fairly rapidly to its source. As the river-volume is often irregular and intermittent, or locally insufficient, water must be stored or conserved. Britain has no glacial ice-cap to store winter precipitation against summer demands and drought, and we must depend on reservoir storage overground and natural storage underground. The water storage capacity of England and Wales overground is now of the order of 200,000 million gallons, which provides these areas with about three months supply of water. But although this is regarded as sufficient insurance at present against there occurring not more than once in ten years a drought as long as the longest known drought, the insurance is not evenly spread throughout the country ; and, in fact, most parts of Britain need to restrict supplies of water if no measurable rain falls for periods in excess of about thirty days. Moreover, this reserve does not take into account the steadily increasing demands.

The natural storage underground of water is largely confined to certain receptive geological formations, notably the chalk. This has a surface outcrop in Britain of some 5,000 square miles which, catching an average of some 20 inches of rain a year, gives an annual yield potential of some 750,000 million gallons. Other important aquifiers are the Midland Oolites, covering 2,000 square miles, with a yield potential of 315,000 million gallons yearly ; and the Triassic sandstones, covering 1,750 square miles, with a yield potential of 300,000 million gallons yearly. With 15 per cent of our present consumption derived from underground sources, these figures appear reassuring, until we realize that widespread boring and pumping would be necessary to tap all the available resources, which again are not always in the right places. Furthermore, the utilization of these supplies needs careful management. Reports of falling water-tables from nearly all areas using ground-water are commonplace and indicate a rate of extraction in excess of replenishment. Present withdrawals for the 10 million inhabitants of the London Basin take some 260 million gallons daily from the chalk : records show a steady fall in the water-table here for the past hundred years. In the Thames Estuary the hydrostatic level is now several hundred feet below sea-level, and the seepage of brackish water is causing concern. The Water Act of 1945 now forbids the boring of further wells in the City of London without a licence from the Ministry of Housing and Local Government.

The total water supply in Great Britain is clearly adequate ; but it is of little use unless it is available in the right place at the right time. Nature unfortunately distributes it very unevenly in both time and space. How are we to escape from this dilemma ? Clearly more water could be impounded in reservoirs ; but there is an obvious economic limit to this process, for it consumes much-needed land and disturbs many interests. There is the possibility of a much higher standard of watershed management to hold back the run-off and so conserve supplies. Artificial recharge of underground sources now suffering depletion could also be practised, as in the United States and the Netherlands. In the London Basin, some 150,000 million gallons of the Thames flow might be preserved in this way. The use of sea water is also possible where salinity is no objection, although this produces problems of corrosion in pipes. The desalting of ocean water as well as cloud seeding to induce rainfall are probably as yet uneconomic.

The idea of a national water grid for Britain has occasionally been mooted, and indeed found a place in the Labour Party's election manifesto of 1950. But water, although an equally important public utility, is not like gas or electricity: it largely depends on gravity for natural movement, and many doubts have been cast upon the economic and engineering feasibility of a national water grid. At the present time, there are some 1,100 water undertakings in England and Wales responsible for providing public supplies. More than 900 are local authority organizations, some 115 are statutory water companies, 54 joint water boards and 47 smaller non-statutory water companies. There has been a tendency for smaller water authorities to be absorbed by the larger and for joint boards to be formed; but there is still a great number of separate undertakings. In addition to these public supply authorities, there are innumerable private water developers: for example, in the City of London more than a hundred 'wells' supply office and industrial buildings. There is thus a great multiplicity of water undertakers all working independently and very often against each other; and the problem which is looming ahead is being nibbled at piecemeal all over the country.

There thus seems strong grounds for an over-all national water policy, and this was, in fact, envisaged in the Water Act of 1945, which imposed upon the Minister of Health the duty, since transferred to the Minister of Housing and Local Government, "to promote the conservation and proper use of water resources and the provision of water supplies in England and Wales, and to secure the effective execution by water undertakers, under his control and direction, of a national policy relating to water". The necessary administrative organization to achieve this has, however, been slow to emerge, and many complaints have been voiced. The Minister did not set up the regional advisory committees which the Water Act empowered him to appoint. The River Boards Act of 1948 set up boards responsible to the Minister of Agriculture. The Central Advisory Water Committee lapsed in 1952, and the Inland Water Survey was suspended as an economy measure in the same year (see *Nature*, November 7, p. 823, 1953; and *The Times*, March 24, 1954); and the industry has complained that it has been allowed too little capital investment in comparison with other national utilities. (Manchester's Haweswater Reservoir, which was completed in 1941, had not been tapped by 1949 because of restrictions.)

The water industry has proposed the formation a 'Water Commission' separate from, but appointe by and answerable to, the Minister of Housing an Local Government. This idea has been formally submitted to the Ministry by the British Waterwor Association, but appears to have found little favou Since this action the United Nations Economic an Social Council, in a report on Development an Utilization of Water Resources (London: U.N Information Centre, 1954), has recommended "tha each country would be well advised to set up a wate board or water commission at cabinet level". It envisaged that such a water board would hav representatives of all interested government departments and local government bodies concerned wit the numerous aspects of water conservation an utilization. The problem of supply could be looke at as a whole and suitable policies formulated. Th need clearly exists in Great Britain, as elsewhere, an the recent decision of the Minister of Housing an Local Government to revive and reconstitute th Central Advisory Water Committee is a welcome ste in the right direction (*Nature*, October 22, p. 76 and November 12, p. 908). This Committee is now t consider the extent to which the demand for wate is likely to increase and also the ways and means o collecting hydrological data, and will then mak recommendations. Its report will be awaited wit interest, for this problem is closely related to that o flood control, which, as has already been emphasize in these columns (*Nature*, 172, 263 and 823; 1953) also merits more detailed attention. Without muc careful thought and more vigorous action, we mus inevitably move in the future into the paradoxica situation of increasing water shortages amid plentifu precipitation and recurrent flooding.

# THE THREAT TO SCIENCE

A STRIKING picture of the dangers whic confront men of science has been prepare recently by Gerard Piel, publisher of *Scientifi American*, one of America's leading magazines (*Bull Atomic Scientists*, 11, No. 7; September 1955). At th outbreak of the Second World War, he writes, scienc was a kind of ideal world republic. The scientifi community was an international community. It wa the only truly international community at an epoc that was to see nationalism and the narrower concern of national power rise again to ascendancy in worl politics.

Statesmen discovered early in the War that scienc is an essential element of national strength. To-day they rank it as equal in importance to their industria and military establishments. Accordingly, eac major power has sought to monopolize the talents o its scientists and to put them to work in the nam of national security. This suppression of internationa motives in favour of national ends has now ha serious consequences upon the life of science. Th situation in the United States provides an extrem case of what, to a greater or lesser degree, has bee happening in other nations.

Scientists are agreed, in the first place, that there as been a dangerous diversion of resources and alent from the really significant long-range concerns f science to the narrower short-range objectives of ractical results. Nearly half America's expenditure ach year goes to armaments. Economic and social ressures have moved a disproportionate percentage f the inadequate supply of scientists from univerities to government and industrial laboratories. Even in American universities, the work of science as become dependent upon income from outside ontracts and subject to the outside motivations which such contracts imply. As a result, the careers f an alarming number of the younger generation of cientists are now permanently lost to science. The ducation of the next generation is jeopardized by he breakdown of science teaching in American high chools and colleges. The future of science has been mortgaged in the eagerness to exploit its past.

Science has come under another kind of duress hrough preoccupation with national security in the arrow and negative technical sense of the term. Military secrecy seriously hampers publication and ommunication in a number of major fields of work. Direct contact between scientists has been disrupted by restriction on the travel of American scientists abroad and the admission of foreign scientists to America. Scientists have been among the most notable victims of the invasion and abuse of personal privacy and dignity which characterize the loyalty and security programme of the Federal Government. Outside any conceivable connexion to national ecurity, the attendant obsession with loyalty has reated an atmosphere of fear and conformity which s as obnoxious and stifling to science as to any other branch of free inquiry.

It is impossible to calculate the damage that has been done to the integrity and vitality of the American cientific establishment. "Without doubt we shall pay for it in the future. It will show up in the loss f the advances in technology which should have ome from the progress in science we have set aside oday."

There is a lesson in this recital. The scientific nterprise cannot be successfully subordinated to merely national ends. Without the long view—the world view—the advance of science must falter and ome at last to a halt.

The international tradition runs too deep in the fe of science, however, to have been throttled in fteen years. Among scientists in every field, their ersonal and professional associations with colleagues broad, their mutual respect for one another, and the sharing of achievement in significant work estabsh bonds which outreach the dividing movements f this period. The international community of cience still provides us with our most hopeful xample of a world polity, in which statesmen and itizens as well as scientists may some day participate.

In the rest of his article Piel points to activities ke the International Geophysical Year and the work f the United Nations Technical Agencies as examples f those forces which should serve as hope and ncouragement to men of science everywhere.

# MODERN CYTOLOGY

International Review of Cytology
Edited by G. H. Bourne and J. F. Danielli. Vol. 4. Pp. xii+419. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 9 dollars.

As usual, Dr. G. H. Bourne and Prof. J. F. Danielli have selected widely different topics for Vol. 4 of the "International Review of Cytology". While many readers might well ask for more unity, I thoroughly enjoy this non-conformist lack of uniformity. The articles in which I am directly interested are extremely useful and valuable for my research work; the others are no less important for a teacher in general biology.

The first paper, by M. J. Kopac, deals with cytochemical surgery: the list of the methods and the instruments available for quantitative cytochemical investigations on isolated cells or their parts is very complete; but the descriptions are somewhat too short to enable one to utilize them without going back to the original papers. A new "volumetric submicromanipulator" and a modified microdilatometric method are described; they should prove useful, but it is perhaps unfortunate that the results obtained so far with them—if there are any—are not mentioned.

After an interesting article on amœbocytes, especially in molluscs, by L. E. Wagge, M. Wolman discusses cytological and cytochemical fixations: the expected conclusion is that even freeze-drying is far from ideal and that there are no good universal fixing-agents. The next two papers, by A. Marshak and by R. Vendrely, deal respectively with bacterial cytology and histochemistry (the latter a rather ill-chosen title, since bacteria scarcely constitute a tissue in the usual sense). They are well documented, but their very carefulness leaves the reader with a slight feeling of frustration; he will often have to draw his own conclusions.

Next come reviews on plant mitochondria (D. P. Hackett) and the structure of chloroplasts (K. Mühlethaler); we are here on safer ground, and there seems to be little reason to doubt that plant mitochondria strongly resemble animal mitochondria, and that the structurally complex chloroplasts originate from proplastids distinct from the mitochondria. N. B. Kurnick's review on the histochemistry of nucleic acids is very thorough and critical; although it only deals with the techniques, it should prove very useful.

The article on structure and chemistry of nucleoli, by W. S. Vincent, is clear and contains much new information; the author reaches the conclusion that the nucleolus might be the site of a limiting rate-reaction necessary for the maintenance of cytoplasmic syntheses. With H. Moe and R. Couteaux the reader comes back to more orthodox cytology: the former writes about goblet cells, the latter about the localization of cholinesterase at neuromuscular junctions. Both papers are very well illustrated. Finally, E. J. Conway surveys the evidence in favour of a redox pump in the active transport of cations, and shows that this hypothesis adequately explains many facts in yeast cells as well as frog skin, gastric mucosa or plants.

The book is very well produced; the unfortunate consequence is its rather high price. There are extremely few misprints—usually names of authors quoted in the text or in the bibliography; but why is it that the only two words quoted in French are wrongly spelt?

J. Brachet

## STRATIGRAPHICAL PALÆONTOLOGY

**Stratigraphical Palæontology**

A Study of Ancient Life-Provinces. By Dr. E. Neaverson. Second edition, revised and enlarged. Pp. xii+806+18 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 105s. net.

THIS second edition of Dr. E. Neaverson's text-book has been awaited with much interest. The earlier filled a gap of which teachers of palæontology were well aware. It was the first attempt at producing, in Britain, a book dealing with the application of palæontology to stratigraphy, and giving a general account of the succession of faunas and floras throughout the Earth's history. The remaining stocks of this book were destroyed towards the end of the Second World War as a result of enemy action, and the author, in preparing a second edition to make good this loss, has taken the opportunity of revising and augmenting the original. The chapter dealing with the morphology of fossils, more appropriate to a text-book of general palæontology, has been omitted. On the other hand, the account of the marine faunas has been usefully augmented to include details of their occurrences outside Britain. Three more chapters have been added to deal with the vertebrate land faunas of the several continents, and in a final chapter the relationships of the continents as revealed by their past faunas are discussed.

Dr. Neaverson has gathered together a vast amount of information from numerous and scattered sources to make a book which should be invaluable to teachers, no less than students, of stratigraphy. Unfortunately, it is now in size and cost more of a book of reference than a text-book that every student could be expected to buy. The emphasis is on the zoo-geographical aspect in that the faunas are discussed *seriatim* under the various systems so that evolutionary changes are difficult to follow. Since stratigraphical subdivisions are largely based on such changes, a clearer picture of the dependence of stratigraphy on palæontology might have been given if the history of each phylum in turn had been traced throughout the geological record. This treatment has, in fact, been partly accorded to the fossil plants, the account of which is oddly placed in the middle of the book between "Carboniferous Faunas" and "Tetrapod Faunas of the Late Palæozoic System".

The accounts of the faunas of each system are comprehensive and well documented. They assume in the reader a fairly high standard of stratigraphical and palæontological knowledge, but could have been made much easier to digest by the provision of good palæogeographical maps in place of the numerous peculiar and not very informative maps on which the distribution of rocks is shown by crosses, circles and black disks.

In these days, when the economic aspect of geology is more important than ever before, it is to be regretted that Dr. Neaverson, in common with many other teachers of palæontology, has paid so little regard to the microfossils. Less than a page is devoted to the Ostracoda. The larger Foraminifera are paid a little more attention, but no indication is given that there are large and varied microfaunas in almost every formation since the Cambrian, some of which are used daily as guides to stratigraphy. The last chapter, on the relationships of continents and oceans, is interesting in its treatment of a complex and difficul subject but would, nevertheless, have been bette omitted. The subject is perforce dealt with to superficially, and the evidence is not discusse entirely without bias.

The book is well indexed and includes eightee excellent plates figuring a number of fossil specie though the selection is a little unbalanced: one plat is devoted to nummulites, three to brachiopods, n less than eleven to the cephalopods, one to lamellibranchs and two to echinoids. F. W. ANDERSON

## MATHEMATICS FOR BIOLOGISTS

**Biomathematics**

The Principles of Mathematics for Students of Biological Science. By Dr. Cedric A. B. Smith. (Bein the Third Edition and a rewritten version of th work by the late W. M. Feldman, M.D.) Pp. xv+712 (London: Charles Griffin and Co., Ltd., 1954.) 80s. net

NEARLY eighty years ago Charles Darwi described in his autobiography how the stud of mathematics had been repugnant to him in hi early days, and then went on to deplore his consequent lack of understanding of mathematica principles, adding in explanation, "for men thu endowed seem to have an extra sense". How ofte must Darwin's words have been echoed by biologists especially with the tremendous increase of quantitative treatment in biology during the past thirt years or so. This great trend towards the quantitativ has been most striking in the laying out of experiments and the interpretation of results; but it is t be seen also, and no less characteristically, in th growing use of mathematics for the development o biological theory. Biologists are in fact being face with an increasingly insistent demand for capacity as well as willingness, to utilize the tools whic mathematics offers. Willy-nilly they will have to b prepared, in growing numbers, to acquire and use a least some mathematical skill; and they will nee books to help them to do so.

There is now no shortage of books dealing at variety of levels with mathematical aspects of th acquisition, analysis and interpretation of biologica data; but Dr. C. A. B. Smith has set out to meet different need. In rewriting "Biomathematics" h has followed the late W. M. Feldman, to whom th two earlier editions were due, in aiming at a presentation of the fundamentals of mathematics as such, s that the biologist should be able to see for himsel how his problem can be handled mathematically. Starting with an account of arithmetic procedures, including those appropriate to calculating machine and punched cards, the book goes on to cover a great deal of ground including not only the more familia principles of algebra and geometry but also inequalities, series, integral as well as differential calculus, vectors, matrices and statistical theory.

By mathematical standards the treatment is doubtless very largely introductory; but the biologist will find here a wealth of notions and methods such as can scarcely have been available to him before within the covers of a single volume. He must not expect to find the going always easy, as Dr. Smith indeed warns his readers on p. 1, and probably few biologists will take the full course of seven hundred pages without some skipping. Some parts, such as, for xample, those dealing with the solution to equations, nomograms and probability, will inevitably be more widely read because they deal with requirements which arise more widely in practice. In fact, although his may not bring out its full value, "Biomathematics" is likely to be used chiefly as a reference book to be dipped into as the need arises, and its use n this way will be all the easier for the glossary of ymbols provided at the beginning. The need for such a source of mathematical reference is more widespread than even biologists themselves probably eel.

So long a mathematical book can scarcely fail to be expensive, and it is perhaps an inevitable misfortune that at 80*s*. the price of "Biomathematics" will limit its sale. It is to be hoped, nevertheless, hat younger biologists will at least have ready access to Dr. Smith's book in their laboratories, and will be encouraged to use it. For, given the opporunity, it can offer much-needed help. K. Mather

## PRINCIPLES OF ANALYTICAL INORGANIC CHEMISTRY

Grundlagen der analytischen Chemie und der Chemie in wässerigen Systemen

Von Prof. F. Seel. Pp. 348. (Weinheim/Bergstr.: Verlag Chemie, 1955.) 29 D. marks.

THIS book deals in five chapters with the separation of metal ions by precipitation techniques, eactions in molten salts, various volumetric titrations and electrolytic separation methods. In twenty hapters problems of more general interest are set out: namely, definitions and fundamental theories, mass action law, solubilities, theories of precipitation, olloid chemical effects, formation of complexes, proton transfer reactions, acid-base equilibria, ion xchangers and oxidation–reduction processes.

Students who read this book are liable to get an nbalanced view, because the usefulness of the mass ction law in dealing with heterogeneous systems is ver-emphasized and because many important topics re omitted; for example, the relative contributions f $\Delta S$ and $\Delta H$ to $\Delta F$ of a chemical equilibrium, or n appropriate treatment of reaction kinetics and mechanism. Furthermore, there is no coherent story, he presentation being confusing and not consistent. Thus, the mass action law is derived, *ab initio*, in Chapter 2, while the derivation of Nernst's formula, onnecting electromotive force with ionic activities, is only very briefly indicated in an appendix, lthough it is extensively used in the last ten chapters. There are statements such as "reactions with ositive $pK$ values use up energy and reactions with egative $pK$ values yield energy" ($pK$ is the negative ogarithm of the equilibrium coefficient), or "the nergy of dissociation of certain complexes must be erived from a precipitation reaction". In other ections reactions are classed as "inhibited", although t is not suggested that an inhibitor influences the inetics, the failure to reach equilibrium within a hort time being merely due to the energy or entropy f activation. Again, the term "physical" solubility s introduced, implying that this is different from ther solubilities, but there is no definition; and many numerical values of $pK$ are listed, in the text nd in four tables of the appendix, without specifying he temperature.

Advanced research workers and university teachers, on the other hand, should not be unduly disturbed by these and similar shortcomings; but this class of readers, if interested in analytical chemistry, will miss a discussion of colorimetric, flame photometric, chromatographic and polarographic methods, and representative literature references.

It must be pointed out, however, that five out of the twenty-five chapters are rather enjoyable to read, provided they are considered as separate short monographs. These chapters contain instructive numerical calculations and some useful information not given in conventional text-books of analytical chemistry. Albert Wassermann

## LENS THEORY

Theory of Lenses

By E. W. H. Selwyn. (Monographs for Students.) Pp. 62. (London: Institute of Physics, 1955.) 5*s*.

BY the theory of lenses, Mr. E. W. H. Selwyn means a discussion, in terms of physical optics, of the behaviour of real lenses. This book is intended for students preparing for the Higher National Certificate in Applied Physics, and is one of a series bridging the gap between the elementary text-books and the academic and technical treatises. Its outlook is original and refreshing, and the author's long experience of both lenses and learners has enabled him to deal handsomely by both. His aim, he says, is that the reader shall not be too much surprised by some of the things he may notice when using optical devices or trying to make them in the laboratory. One feels that the student who has fully mastered the contents of these few pages will really understand what he is doing in such circumstances, for this is an excellent introduction with a very practical approach.

After an initial discussion of the wave theory of light, in which the beginner's difficulties with Huygens's construction are admirably resolved, the author traces the effect of a refracting surface on a wave-front diverging from a point, considering in turn the image formed by a spherical refracted wave-front corresponding to paraxial conditions, and the distortion of this wave-front due to aberrations. A fair knowledge of co-ordinate geometry is here assumed; but the mathematical treatment is clear and straightforward. Next, the terms in the expression for the distorted wave-front corresponding to the second-order Seidel aberrations are identified, and their effects on the image and their correction are explained. The last chapter deals with correction for colour, high-order aberrations, and the balancing procedure of the lens designer in achieving some cancellation of one aberration by a higher-order aberration of the same kind.

The book ends with a selection of problems, some simple exercises on the book-work and some particularly searching ones. None, says Mr. Selwyn, can be solved merely by substituting numerical values in a correctly remembered formula,—a comment which the late Prof. John Perry might have expanded into many vehement paragraphs, and which conveys all too delicately a warning against the student's greatest temptation. But the reader who has followed Mr. Selwyn's treatment will naturally be thinking in terms of physics rather than of formulæ, so that perhaps even so gentle a reminder may prove superfluous. G. R. Noakes

## Higher Transcendental Functions

Vol. 3. Based, in part, on notes left by the late Prof. Harry Bateman, and compiled by the Staff of the Bateman Manuscript Project. Edited by A. Erdélyi. (Sponsored by the California Institute of Technology.) Pp. xvii+292. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 49s.

THE third and final volume of this work, consisting of Chapters 14–19, deals mainly with problems much less tractable than those discussed in the previous volumes. Chapter 14 contains an interesting account of automorphic functions, a subject more akin to algebra than to analysis. It includes a summary of the theory, with references to text-books and research papers for those desiring to pursue the subject.

Chapters 15 and 16, on Lamé and Mathieu functions respectively, are concerned with differential equations the solutions of which are not expressible in hypergeometric form. As there is no general agreement about standard types of solutions, and as the formulæ are long and complicated, the editors have been forced to make a selection. In the case of the Lamé functions they have, wisely I think, employed the Jacobian elliptic functions; while in the chapter on the Mathieu functions they have followed McLachlan's well-known text-book. Abelian functions and multiply-periodic functions, for the discussion of which at one time large tomes were required, are only briefly referred to. Does a like fate await the Lamé and Mathieu functions? In addition to the Mathieu functions, Chapter 16 has sections devoted to spheroidal wave-functions and ellipsoidal wave-functions.

Chapter 17 contains an account of the functions of number theory. It is scarcely full enough for beginners in the subject, but may be useful to them as a guide; to the research worker the references will, of course, be useful. There follows a chapter on miscellaneous functions, such as Mittag-Leffler's and Wright's generalizations of the exponential and Bessel functions. In the final chapter is to be found a simple and interesting account of generating functions. The editors are to be congratulated on the completion of a most helpful aid to research in this field of mathematics. T. M. MacRobert

## Progress in Cosmic Ray Physics

Edited by Dr. J. G. Wilson. Vol. 2. Pp. xi+322. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1954.) 45 florins.

THIS book continues worthily the work of the previous volume in presenting reviews of interesting topics in cosmic-ray research, primarily for the benefit of specialists in this subject and those closely adjacent. Many such people will already have used the book. Since this book was mainly written in 1952, and since this review appears late, it is necessary to indicate which portions have been seriously outdated. Unfortunately, Dr. J. G. Wilson's discussion of the unstable particles was written before the 1953 Bagnères conference at which the position about these particles was notably cleared. This conference now forms the best starting-point for the study of these particles. For the future, data from high-energy accelerating machines will probably lead to a rapid increase in the amount of information.

Prof. R. D. Sard's article on the nuclear interactions of $\mu$-mesons at rest remains topical, but might need to be more closely tied to the investigation of mesonic atoms. Prof. H. Messel's article on th development of a nucleon cascade is the most con venient presentation of his theoretical work on subject which is under actual experimental investi gation at a number of centres. The article b Dr. L. Voyvodic is a valuable introduction to th technique of interpreting particle tracks in nuclea emulsion.

## An Introduction to Deductive Logic

By Prof. Hughes Leblanc. Pp. xii+424. (Nev York: John Wiley and Sons, Inc.; London Chapman and Hall, Ltd., 1955.) 38s. net.

THE study of logic in its various forms is makin rapid progress; and in some American univer sities it is accepted as an undergraduate course. Thi much is clear from the number of college texts whic appear regularly, many of them valuable in par ticular fields. This one is distinguished for th delicate balance it maintains between philosoph and mathematics. In this way it provides—give the requisite degree of direction from a competen teacher—a very good guide to deductive logic.

In Great Britain, where the emphasis betwee theory and practice is a little different, a course o this kind might well help forward the training o physicists (including theoretical physicists), who migh later become theoretical biologists, capable of copin with the structure of systems of immense complexity The future, both national and academic, seems t need able thinkers orientated towards deductiv logic. Training in some parts of the subject migh also be expected to help in communication theory.

This book by Prof. H. Leblanc contains a coupl of chapters devoted to two-valued and many-value logics (including modal logic), coupled with 'classical and intuitionist quantifiers. Then he discusses, among other topics, identity, classes and relations. Finally, comes a study of syntax. While there i nothing strikingly new in all this, the author ha contributed something of value to the education o non-specialists which should assuredly yield worth-while results. F. I. G. Rawlins

## Science News, No. 37

Edited by A. W. Haslett. Pp. 128+16 plates. (Harmondsworth, Mddx.: Penguin Books, Ltd., 1955.) 2s. 6d.

WITH 'automation' the catchword of the moment in industry and elsewhere, it is not surprising that the enterprising editors of "Science News" have included an article on the automatic factory in their latest issue (37). This has been written by Dr. H. D. Turner, and in it he reviews the development of automatic machines, the growth of the automatic factory, and the need for functional thinking about technology to ensure that the second industrial revolution may avoid some of the harmful effects on society which accompanied the first. Another interesting article is one by J. B. Collins, who describes the inadequacies of existing artificial illumination and gives some pointers for research. The revolution in physics and philosophy brought about since Einstein published his first work on relativity fifty years ago are discussed by W. B. Bonnor. Other articles are by Prof. Kathleen Lonsdale, who writes about neutrons and atom patterns in crystals, and by Prof. J. B. Cragg, who examines the ecologist's role in Nature conservation. The general editor, A. W. Haslett, contributes his usual research report on a wide range of topics.

# THE CHROMOSOME AS A PHYSICO-CHEMICAL ENTITY[*]

By Prof. C. D. DARLINGTON, F.R.S.
Botany Department, University of Oxford

## 1. Deoxyribonucleic Acid and Protein

SOON after the description of mitosis in 1878 its uniform mechanical character led German biologists to point out that uniform physiological properties were to be inferred in the chromosomes taking part. From this beginning the way has led inevitably to the recognition that chromosome behaviour had two aspects, physical and biological, that the second was the expression of the first and that, ultimately, the two must be seen together as a whole. Twenty years ago it was possible, following this view, to set out certain principles of chromosome mechanics and take note of a family of problems arising from them[1]; possible, that is, by the severe neglect of secondary details. Since that time, advances in the physics and chemistry of the chromosomes have brought the two sides within speaking distance.

These advances include two revolutions in our knowledge. The first depended on Caspersson's discovery that the chromosomes consisted characteristically of a combination of protein and deoxyribonucleic acid (DNA), which are jointly concerned in their reproduction and in their other activities[2]. Reproduction is, of course, a property equally of DNA-protein in the chromosomes and ribonucleic acid (RNA)-protein in viruses and other particles of the cytoplasm. Equally for both, Astbury showed that the peptide and nucleotide chains fit one another so that a template principle might apply[3]. This suggestion still seems fundamental, although the mode of fitting is debatable. On Caspersson's view, however, the DNA was accessory to the protein chain; their attachment was reversible in the nuclear cycle and discontinuous along the length of the chromosome, being interrupted in the stretched fibres between the staining units.

The second revolution disturbs this part of the account. The content of DNA does not, it seems, fall in the resting nucleus but remains constant until it increases in the course of reproduction. Thus DNA may well be at least as constant and continuous a structural component of the chromosome as any protein that it may contain.

Several kinds of evidence contribute to this view and carry it even further. Isolated sperm heads[4] and isolated chromosomes[5] have been shown to consist of DNA and protein and a small and variable quantity of RNA. Now the protein varies in character. It is supposed to be largely histone in body-cell nuclei of animals. But, in fish sperm (which carry, in a sense, an India paper edition of the nucleus) it is largely protamine, a smaller molecule than histone, with a different amino-acid content[6]. Other 'residual proteins' in nuclei, moreover, vary in quantity[7].

For the DNA, on the other hand, several kinds of evidence have been obtained in favour of constancy. In regard to quantity, Boivin[8] and Mirsky[9] and their collaborators have shown that a nucleus with a standard chromosome complement (and I shall return later to define what this means) contains a constant amount of DNA. In regard to quality, Chargaff[10] and others have shown that DNA (unlike RNA, which varies from tissue to tissue) has nucleotide proportions in terms of purine and pyrimidine bases. characteristic of the chromosome complement, or the sum of the genes, or the genotype. The analogy here is with the letters in a book the proportions of which differ in different works but are constant in one work or at least one edition. The infinite diversity of words, or of genes, is not, of course, revealed by quantitative analysis of whole books or whole nuclei in terms of these smaller units.

A second property of DNA revealed by these determinations has been the equality in number of the large purine and the small pyrimidine bases. This, together with the crystallographic picture and the template principle, has suggested a new model of DNA[11]. According to Watson and Crick, the DNA normally exists in the chromosome as a double and coiled nucleotide column, each side of which, if separated from its partner, can act as a template for the assembling of the other. On this basis DNA would appear as a self-sufficient genetic structure with the protein at least mechanically subordinate. But, of course, we do not need to take such an extreme view: equality and reciprocity are also conceivable.

This new knowledge leaves some uncertainties and a few apparent contradictions. But it allows us to reconsider the rules governing a part of chromosome behaviour, those concerned with changes of shape within the nucleus, which I have called the internal mechanics of chromosomes. It allows us to find out how far the micron point of view agrees with the angstrom point of view.

## 2. Spiralization

The reproductive or mitotic cycle of the nucleus depends on the alternation of two states, the nucleus and the chromosomes, each of which is stable in its internal mechanics. In the metaphase or most contracted state of the chromosomes the gene-strings are packed for transit in a small, if not the smallest, bulk; and the genes themselves are inactive. In the resting nucleus the chromosomes have absorbed water and have swollen to tens or hundreds of times their metaphase bulk. The genes are, or at least may be, engaged in reproducing themselves and in producing also RNA (ribonucleic acid) and proteins. Both these, partly by way of a special globular structure, the nucleolus[12], are believed to pass into the cytoplasm; but their relative importance is debatable, like that of the DNA and protein in the reproduction of the chromosome.

The physiological activity of the chromosomes is shown very easily. Nuclei which differ in content of

---

[*] Substance of a paper to Section B (Chemistry) of the British Association meeting at Bristol read on September 1.

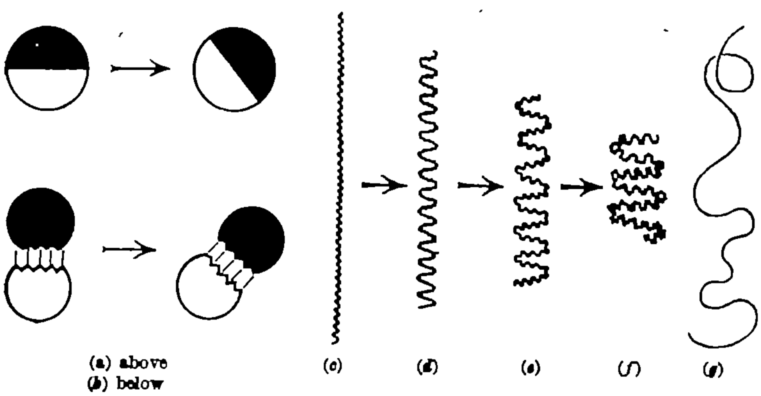

Fig. 1. The three levels of spiral formation. (a) twisting, an internal-molecular change; (b) rolling, a relational change demonstrating the pairing face; (c, d, e, f) coiling stages in the successive development of major, minor and perhaps third-order coils during prophase; (g) relic coiling formed by relaxation in the resting nucleus

genes are regularly produced in the spores which arise at meiosis in most plants: and when they differ the spores diverge in the rate of their growth, a divergence which is the basis of fertility and sterility in plants. The reproductive activity of the chromosomes, on the other hand, shows itself in their double structure: when they appear at the beginning of the next mitosis they have divided into pairs of chromatids. This change is reflected in the doubled DNA content of the nucleus[13].

Side by side with the physiological cycle of mitosis there is also a mechanical cycle which has been called a spiralization cycle. In the first stage or prophase of mitosis each chromosome consists of paired chromatids arising from reproduction. These separately assume a helical or coiled structure which reduces their length to about one-tenth at the metaphase stage[14]. When the chromatids reconstitute daughter nuclei at the end of mitosis by absorbing water, they stretch these coils; but movement is limited by space and the coils fail to straighten. By a kind of hysteresis they are retained right through to the next mitosis, where they reappear as relic coils. The minute incipient internal coils[1] arise quite independently of the large decaying relic coils (Fig. 1).

Three questions now arise. (1) How is the coiling set up? (2) What determines its direction, whether left- or right-handed? (3) Is the visible coiling sufficient to account for all changes in length?

(1) The coiling might be set up by rotation of the ends, just as we coil a piece of wire; if, that is, any outside force were conceivable that could twist ends of fibres in a cell against the resistance of the fibres themselves. This idea, however, is quite excluded by the fact that chromosomes, which have no ends at all, can take a spiral form. In various plants where ring chromosomes have been produced experimentally, they meet with frequent accidents. But they can take a spiral form and they can reproduce. Moreover, in *Drosophila* they propagate themselves well enough to keep the fly alive and, what is more remarkable, allow it to pass them on to its progeny after a due amount of crossing-over[15].

Scarcely less decisive is the evidence of complexes in which all rotation has been stopped by an experimental breakage and reunion of chromatids, which can unite in one body the whole chromosome complement[16]. On such grounds the force setting up coiling must be supposed to b
internal. There must be a mol
cular twist which determines an
at the same time compensat
for the internal coiling (Fig. 1
Now the daughter rings which
ring chromosome produces fa
apart, usually without interlock
ing: this molecular twist mus
therefore at the same time gover
the direction of reproduction of
ring chromosome. In other word
each chromosome must be sup
posed to have a reproductive o
splitting or cleavage face which i
continuous throughout its lengt
and continuous also throughout th
mitotic cycle.

(2) The direction of coiling o
chromosomes is another matte
Left and right systems are foun
together in the same nucleus and, in diploid nucle
in the same pair of chromosomes. The direction is
however, probably constant for each arm of
chromosome at each mitosis. Now, if the directio
of twisting as well as the capacity for twisting wer
inherent in each piece of chromosome, the exchang
of pieces which is continually going on in the cours
of evolution would have led to utter disorder lon
ago. The direction, therefore, must be under unitar
control. Probably the agent is the centromere, th
non-spiralizing group of genes which, in each chromo
some, influences or directs all movements, includin
chemical movements, in which the chromosome ha
to behave as a unit (Figs. 2, 3 and 4).

(3) The answer to the third question is given b
certain resting nuclei of glandular cells in flies. I
the salivary glands, for example, the chromosome
are visible in the resting nuclei and are probabl
stretched to as much as three hundred times thei

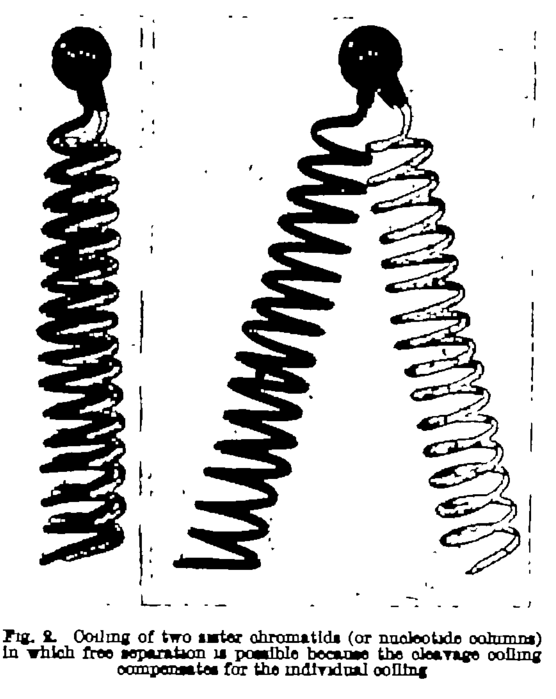

Fig. 2. Coiling of two sister chromatids (or nucleotide columns) in which free separation is possible because the cleavage coiling compensates for the individual coiling

minimum length[14]. Clearly, the single visible coil of mitosis is not enough to account for this degree of change. Part of the explanation is revealed at meiosis.

Meiosis is a distinct type of mitosis in which corresponding chromosomes pair, a process I shall return o later. So far as coiling is concerned, however, the metaphase chromosomes at meiosis show two special features. The first is that the paired chromatids may coil, not separately to form two rods as at mitosis, but jointly to form a single rod. When they do so, however, they are still capable of falling apart instantaneously when the chromosomes move to opposite poles (Fig. 2). In other words, we again have a strictly compensating coil and a strict cleavage face as in ring chromosomes.

The second feature of meiotic coiling is that a minor spiral (first described by Fujii in 1926) can be seen beneath or within the major spiral (Fig. 3). This two-order system of coiling goes with a greater shortening of the chromosomes. But since all degrees of shortening occur, we may suppose that there are two orders of coiling equally at mitosis and meiosis. Indeed, in view of the stretching of salivary-gland chromosomes, we may expect yet a third and lowest order of coiling or folding beyond the resolution of visible light.

How do these systems of coiling develop ? All visible coiling gets larger in amplitude as its develops, a principle which even extends to the last stage of relic coiling. Might there not be, therefore, an indefinite succession of coilings following one another ? The answer to these questions depends on another unknown which we may now consider.

## 3. Polynemy

The characteristic structure of a polypeptide chain or a nucleic acid or a chromosome depends on the lengthwise repetition or polymerization of a unit to give a fibre. The reproduction of a chromosome depends on a cross-wise repetition, a lateral polymerization, of the fibre. But is the chromosome itself a single ultimate unit ? Until recently, this was assumed. But the double nucleotide column at once doubles the minimum element. The biological evidence goes further than this.

Natural protein fibres are usually in bundles. Under certain special treatment, genes and chromosomes can behave as though they were composed of such bundles the constituents of which are capable of mutating or breaking independently[16]. The appearance or emergence of a mutation is then delayed several cell generations[17]: in *Amoeba* five generations suggest thirty-two fibres[18]. The effect of a break followed by reunion is to cause the appearance in the cell of exchanges looking like chiasmata. But they are exchanges between fractions of chromatids.

What does this mean ? An analogy is helpful. The chromosome in genetics has a validity like that of the atom in chemistry, unconditional for ordinary purposes but conditional for extraordinary purposes. Under ordinary conditions, in normal mitosis and normal reproduction, the chromosome acts as a unit. But under extraordinary treatments the unit is decomposed and forces us to admit that it is, after all, a bundle of fibres.

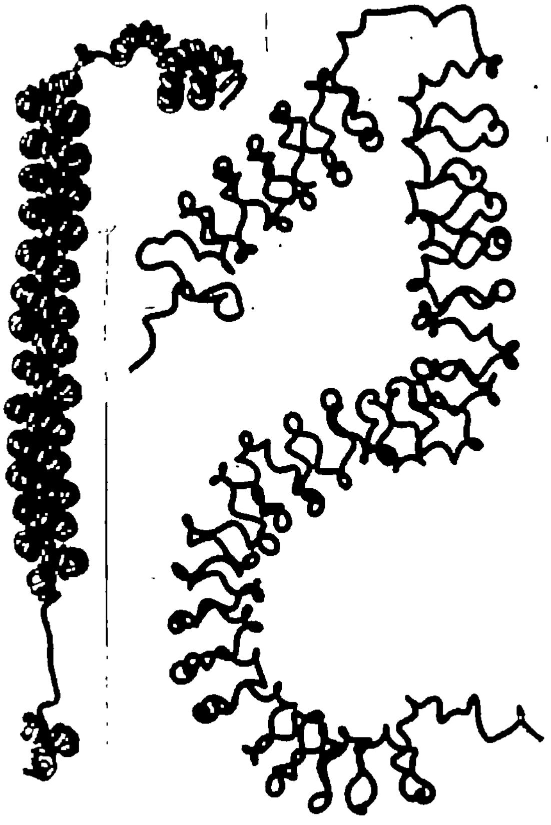

Fig. 3. Double system of coiling in a chromatid as seen at first anaphase of meiosis, and relaxed as relic coils in the ensuing resting nucleus

How many fibres ? We can make only comparative estimates. Closely related plants and animals with similar numbers and shapes of chromosomes often show wide differences in size. A range of the order of 128 : 1 seems indisputable, and it may be much higher[19]. Within the same organism a reduction of size to one-eighth has been found[20]. This happens only in blind-alley tissues of plants. In animals, however, of many groups, repeated chromosome halving is characteristic of the cleavage divisions of the egg[21,22]. In DNA economy, for which cleavage is a crisis, this seems to be the counterpart of 'diminution' in *Ascaris*. But it is a reversible diminution, for in the germ line the size must later be restored completely. In the body cells, on the other hand, we do not know that restoration is always complete: chromosome size, like chromosome number, may sometimes vary from tissue to tissue. Again, following X-raying of roots, chromosomes have been found to come into mitosis at about half their standard size[23]. Conversely, in haploid newts, the chromosomes are said to keep double their normal size, compensating, as it were, for the deficiency in numbers[11].

Can different degrees of multiplication, of polynemy as we may call it, occur in the same nucleus or the same chromosome ? Only once, as a result of hybridization, can this be supposed to have been seen. Species within many genera of plants and animals often have corresponding chromosome complements differing in size. These sometimes retain their differences in first crosses. Wanner and Bruhin[24] have succeeded by heat treatment of a species cross in breaking and recombining segments of the thick and thin chromosomes and so producing mosaic chromosomes. Such mosaics have never been found in Nature. It may be that the same general control which keeps all the chromosomes in step in a uniform nucleus can also usually put them right when they have fallen out of step.

Now if we consider the whole range of animals[9] and plants[14] known for their chromosome sizes and their DNA values, we notice that both vary over a range of 1,000 : 1. Where both are known, they vary in proportion : newts and lilies are large, mammals are medium, and fungi small. Again, we have evidence of a uniform nucleo-protein structure in the chromosomes. As a corollary, where we find related species the chromosomes of which are of similar shape but differ in size, we must assume that a difference in cross-wise multiplication, in polynemy, is responsible ; and the more so where the chromosomes vary in size within an individual.

Only the species test has so far been made. Hughes-Schrader has compared the DNA values of two species of the mantid *Liturgousa* which differ in size of chromosomes. One with smaller chromosomes has twice the number of its relative. It is apparently a tetraploid, one of the half-dozen cases known in animal species with sex chromosomes, But the DNA nuclear contents of the two species are the same[9]. Thus the chromosome, by lowering its polynemy, has compensated for raising its polyploidy ; the opposite to the haploid newt. In many plant genera these size and number relations hold[19]. In such genera DNA value may be expected to change with chromosome size.

In this argument, it will be seen, we are inverting the Boivin–Mirsky rule and using it to correct itself. We are using the quantity of DNA to define the complement of chromosomes and hence to reveal where the character of the complement has broken down or may be expected to break down.

A question of analytical practice is also worth noting here. Hitherto it has been convenient to take genotypic, structural and numerical change as the three dimensions of all variation in chromosome behaviour. Here, however, they cease to be sufficient. Polynemy falls in a class by itself, and is best considered as a fourth dimension of variation.

## 4. Reproduction

With the assumption of polynemy there are two levels at which the processes of gene and chromosome reproduction have to be considered : the ultimate unit of nucleo-protein fibre and the whole chromosome bundle, whether of thirty-two units, as has been assumed in *Amoeba*, or 128, as I would suppose in the large-chromosome lilies and amphibians. The unit fibre of the Watson–Crick model requires the separation of the paired and rolled or coiled columns of nucleotides so that each may act as the template in the building up of a new double column. Further, the mutual template relation of nucleotide columns still leaves us in need of a nucleotide template for protein manufacture. This has its ordinary stereochemical problem with the far-reaching implications discussed by Dounce and others[17] ; and it shares the common uncoiling problem of the nucleotides.

A separation, such as would be required for reproduction of the nucleotide and protein columns, would be possible if their coiling itself represented the molecular spiral the existence of which we have long predicted from the evidence of microscopy. Can i be taken by its amplitude to represent the molecula spiral ? The answer depends on two conditions tha are still uncertain : the degree of polynemy that ca be assumed in chromosomes of particular sizes ; an the position that is to be assigned to the protei components, the histones and residual proteins o Mirsky and his collaborators[7].

The reproduction of individual fibres will be th necessary antecedent of the splitting of the whol bundle, unless the chromosome is to step down t half its former size. The evidence of X-ray breakag indicates that this event coincides with the beginnin of mitosis at the moment when the chromosome begin to become spiral and cease to be breakable[18] We may suppose that bundles beyond a certain siz are unstable, the limit being characteristic of par ticular types of cell. A shift in stability will give change in chromosome size up or down. If the shif is in the germ track, the result may even have th character of an evolutionary change and it has bee described as a 'mutation'[19].

## 5. Meiosis

When the splitting of the chromosomes does no coincide with the beginning of mitosis but, on th contrary, follows it and consequently takes plac visibly and publicly, we have the other type o nuclear division : we have meiosis. We then discove several crucial tests of the mode of chromosom reproduction.

At meiosis the chromosomes become visible o 'enter prophase' when still single ; that is, befor they have reproduced and also before they hav completely untwisted. In this state chromosomes o a kind pair, piece by piece, zipwise. There are tw probably universal mechanical properties of thi pairing. First, the association or attraction is limite at any one point to twos, even when, as in polyploids there are three or more of a kind. Secondly, th chromosomes complete their untwisting and in s doing they set up a fourth kind of spiral system, tha of relational coiling. For once they rotate their ends If the pairing and coiling get out of step (as they d in hybrids) the chromosomes snarl like string unde torsion and this upsets their later development Whether the chromosomes roll right or wrong, the must roll around one another until their relationa torsion reaches equilibrium with their interna torsion, the common textile-spinning equilibrium They do not slip. Evidently the chromosome ha a pairing face just as it has a cleavage [fac (Fig. 1,*b*).

Now, it is difficult to see how columns of nucleotide could have such a pairing face when they are alread paired : they are saturated. But columns separated an prepared to attract the components of daughte columns could have a pairing face and might well b limited to attracting one partner. The face of th pairing chromosome appears to do just what the fac of the reproducing chromosome does : it attracts t itself similar particles in similar positions and in equa quantities. But the result is only momentarily th same. Equilibrium is not reached ; or if it is reached it is soon disturbed again. The preparations fo reproduction are continued or resumed. This happen in the following way. Successive units of activit along the chromosome thread, the chromomere (Fig. 4), are continuing to produce the protein which, according to Caspersson, are pushing the

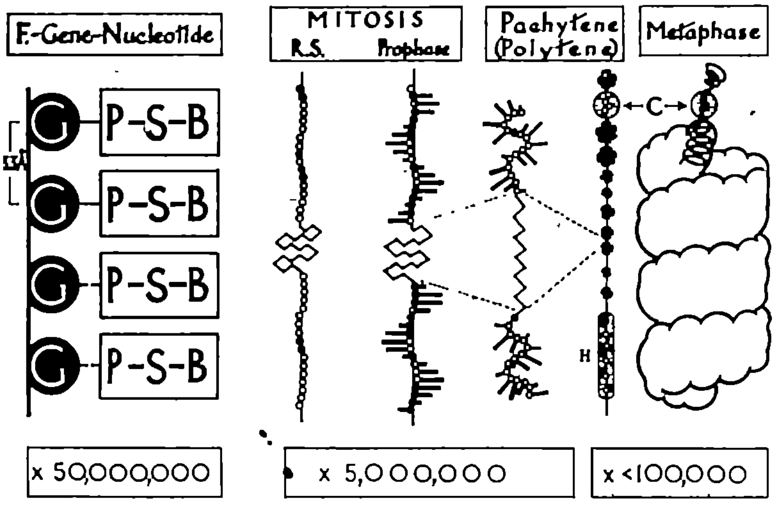

**Fig. 4.** The chromosome considered on the earlier assumption of a single protein thread with a single spiral detachable DNA column and represented at three magnifications

*F*, protein fibre; *R.S.*, resting stage; *C*, centromere; *H*, heterochromatin (reduced from Darlington and Mather, ref. 30)

tion of the parts of genes (Fig. 4). For both vary in different parts of the same chromosome[30] and the same part varies in different tissues of the same organism[31]. These variations must have a molecular basis and that is a problem we have to keep in mind.

## 6. Free Deoxyribonucleic Acid

It is important to see how far we can go with the assumption that DNA is the structural basis of the gene and the chromosome. But we know that DNA can exist in a free state. The occurrence of bacterial transformation shows how important this free state can be. In animal eggs and in the pollen mother cells and pollen grains of plants, reserves of DNA in excess of the nuclear constant have been determined[32], and in the cytoplasm granules containing DNA have been identified[33]. Moreover, there have been found in the Feulgen-staining of chromosomes variations which are related to the capacity for spindle production in the cell at mitosis. This is particularly striking in the differentiation of the mammalian bone marrow, where the red and white blood corpuscle precursors, as described by La Cour, are respectively glutted and starved of DNA; the starved chromosomes are thinner and also longer than the glutted ones[34].

apart and making them visible. The protein and DNA content of the nucleus rises, and when it is doubled[29] the chromosomes split and at the same moment they fall apart.

Thus, although pairing is a substitute for reproduction and may well delay reproduction, it does not prevent it. Why? The rolling or relational coiling of the partners is a sign that the partners are not themselves completely uncoiled at the molecular level and are not therefore attached along one continuous face: the pairing face and the splitting face do not agree. This disagreement may be the reason why pairing is not a substitute for reproduction. The torsion which underlies it is certainly the reason why reproduction is usually followed by a sequence of mechanical changes. For the torsion is released when the chromosomes split into weaker half-threads, the chromatids. It is released by the breakage at corresponding points of pairs of chromatids, their unrolling and reunion in new combinations; all of which together the breeder calls crossing over and the cytologist calls the formation of a chiasma. Both these vary in frequency, as does the torsion which precedes and apparently determines them.

Two points now concern us about these processes. First, the universality and potential uniformity in their time, place and action demonstrate the uniformity in molecular structure of all chromosomes and of their properties of pairing and cleavage. The great range of size and, as we suppose, of polynemy, does not upset the system.

Secondly, a conditionally particulate structure of the chromosome is suggested by chromomeres which can sometimes be seen, and by genes which can correspondingly be inferred. Such a structure, in turn, suggests that only in the intervals between the particles will crossing over usually occur. The chromomeres are condensed regions of coiling or folding joined by stretched fibres which must be weaker. The fewer the number of weak points at which breakage of the two chromatids can occur, the more exactly opposite will the breakage be. It also seems likely that the clustering and folding within chromomeres are related to the physiological integra-

These general variations are to be contrasted with a second type of variations which are cyclical and localized. In many plants and animals there are particular segments of particular chromosomes which seem to accumulate DNA in an unpolymerized or fluid state during the resting stage of the nucleus. These segments are probably groups of smaller and less specific genes[35]. They are known as heterochromatin. Quantitative observations on the cyclical behaviour of heterochromatin are much needed. For the time being we can only say that it appears to differ from the rest of the chromosomes in the rate at which it undergoes mitotic changes, and the difference can be exaggerated at low temperatures. At metaphase, the heterochromatic segments may then appear to be deficient in DNA; they show nucleic acid starvation. They differ from the rest of the chromosomes somewhat as the chromosomes in the white cells differ from those in the red; they are thinner and more weakly staining than the unstarved parts. They remain, however, the same length as when unstarved[35].

In extreme circumstances where there is little heterochromatin in the nucleus, its starvation can also, it seems, be extreme. In certain polyploid plants and in the *X*-chromosome of the hamster[36] and other mammals[37], formation of spirals fails with extreme starvation. This was the first indication we had that DNA was an essential agent in spiral formation, the nucleotides being supposed to be arranged like the steps in a spiral staircase (Fig. 4).

The recent experiments of Mirsky and Ris[7] on isolated chromosomes have carried us a great deal further. They have shown that it is the combination of the polymerized DNA and residual protein (not histone or protamine) which maintains the fibrous structure and thus must determine the forming of spirals of the chromosome. Similarly, the observation that DNA-starved segments show errors of reproduction, sticking of chromatids, was taken to mean that DNA was essential for reproduction of the protein thread. But, of course, we merely notice the DNA because we use it as a marker for staining in routine observation. It would be better, therefore, to say that the protein and DNA are necessary to one another in the right combination.

Are we justified, then, in reconsidering the whole assumption of nucleic acid starvation ? Could we suppose that the starved chromosomes or segments in all these cases are indeed chromosomes which have divided without reproduction of their individual fibres—chromosomes reduced in protein as well as in DNA to half-strength ? On this view, a chromosome with a thin starved segment would be like one in the *Crepis* hybrid between two species with two levels of polynemy.

A number of properties of starvation put this view out of court. First, with local starvation, minute segments of ordinary chromosome can be intercalated in a length of heterochromatin. They are then visible as minute darkly staining points in the starved segment[37]. Secondly, with general starvation and, conversely, with general plethora, there is always a correlation with spindle development and probably general protein production in the cell[38]. Such differences have no parallel in the group of cases where chromosome size is spontaneously or experimentally stepped down.

The two bodies of evidence of DNA as a solely genetic structure on one hand, and as a partly physiological fluid on the other hand, are now in plain contradiction. Before we can resolve this contradiction, however, we shall need to solve problems in the wider field of cell-nucleus relations.

## 7. Cell and Nucleus

The nucleus is the most highly organized part of the cell, and it has hitherto been accessible to more varied modes of experiment and analysis than the cytoplasm around it. It was necessary to establish the nuclear framework of heredity before we filled in the cytoplasmic details. We had to understand nuclear genes before we could invent plasmagenes[40]. So it must be, to some extent, with the chemistry underlying heredity. But we must all the time use the relations of the two, and the relations of chemistry and genetics to keep our bearings.

The predominance of the cytoplasm for the short-term effects which we call physiological and the predominance of the nucleus for the long-term effects which we call genetic, has led to a continual conflict of opinion. On a basis of chemistry and also of microbiology the conflict is being resolved. Nucleus and cytoplasm propagate their enzymatically significant proteins by means of genetic particles, which depend, one on DNA, the other on RNA. The nucleus exerts its long-term control over the cytoplasm by permanently changing its composition ; by passing out into it RNA, perhaps also protein, and exceptionally, also DNA. But, like a good administrator, it delegates as much of its work as possible to the cytoplasm. It delegates the business of respiration to the mitochondria, and as Brachet showed, from the growth of *Acetabularia* cells without nuclei[41], it delegates the routine work of protein production, so far as it is routine work, to the cytoplasm where the RNA-rich microsomes can, no doubt, undertake an unlimited amount of repetitive activity.

The cytoplasm exerts its short-term control over the nucleus not as a rule by changing the composition of the chromosomes, for such changes are irreversible, but by feeding them with materials which either stimulate the activity of certain genes, or provide for the reproduction of all of them. In regard to these alternatives, the cytoplasm differs at the two ends of any cell the products of which are going to follow a different course of development[39]. Similarly, the initiation of meiosis in the nucleus, so often synchronized for large groups of cells, must arise from a sudden change in the cytoplasm, probably the diversion of energy from protein production to processes of nuclear transformation[42].

Our knowledge of the chromosome as a physicochemical entity will continue to be gained in part from these physiological reactions which we can so readily control in our experiments. We have to continue trying, as in the present discussion, to combine ideas expressed in the three languages of the angstrom, the micron, and the naked eye. We may fumble in our efforts to translate ; but in the end we shall learn the same language.

# CHEMISTRY OF THE GRAM-STAINING PROCESS*

By PROF. M. STACEY, F.R.S.
Chemistry Department, University of Birmingham

RIBONUCLEIC ACID (RNA) and deoxyribonucleic acid (DNA) form a high proportion of the organic matter of all bacteria and other micro-organisms. In some yeasts the nucleic acid components may amount to 20 per cent of the dry weight of the cells. While it is quite evident that deoxyribonucleic acid plays a vital part in cell division, constituting, with combined protein, the major part of cell genes and chromosomes, it is by no means clear what are the major functions of ribonucleic acid. Evidence is growing that it plays an important part in protein synthesis, and it also seems to be closely associated with polysaccharide synthesis. Ribonucleic acid forms a high proportion of plant viruses, while deoxyribonucleic acid is present in animal viruses and bacteriophages.

We have tried to discover the significance of both types of nucleic acid on or near the surface of some bacteria, and what connexion they have with the complex surface polysaccharides or 'capsular' components of the bacterial cell.

It is well to remember that there are enormous differences between individual bacteria, and each eventually will have to be treated from the chemical point of view as an individual. Our bacteriological colleagues have built up a vast store of knowledge regarding the activities of all these individuals. By microscopic, staining, fermentation and immunological techniques, it is possible to identify them all rapidly and with great precision. The chemical reasons for the characteristics of morphology and of staining reactions are but little understood. One in particular is the Gram stain, the most commonly used of all bacteriological staining techniques. It consists, as discovered by Christian Gram, a Dane, in 1883, in staining fixed smears with an aqueous solution of a dye of the *p*-rosaniline series and mordanting with aqueous iodine. Subsequent washing with alcohol or acetone removes the dye from so-called 'Gram-negatives' and leaves the 'Gram-positives' stained deeply blue-black. Animal and vegetable cells are not affected by the Gram stain. There are many important microbiological differences between Gram-positives and Gram-negatives. Thus Gram-positives such as the pneumococci usually can be knocked out by chemotherapeutics and antibiotics but give, on injection or after infection, a poor immunity. Gram-negatives, such as the dysentery bacillus, are much less susceptible to chemotherapeutic agents and antibiotics but can give rise to a high degree of immunity.

It seemed apparent that there must be considerable differences between the surface components of Gram-negatives and Gram-positives. Many theories had been put forward in the past to explain the Gram reaction, and most of the early ones were based on studies of the diffusion of the dye through the cell membrane and its subsequent failure to pass out again. Many organisms can readily lose their Gram-positive character under a variety of conditions such as 'old age', treatment with alkalis and acids, and during the process known as autolysis. The resultant Gram-negative cells usually appear smaller and shrunken, and there is an apparent loss of surface material which gives in some cases a reaction for nucleic acids.

With the late Dr. H. Henry we showed that suitable Gram-positive bacteria could be 'stripped' of an essential component of their Gram-positive material by extraction with 2 per cent sodium cholate at 60° C. and thereby rendered Gram-negative. A fraction obtained from material in the extract, itself Gram-negative, could be 'replated' on to the Gram-negative 'cytoskeletons' under reducing conditions to restore in a large measure the Gram-positive characteristics.

This essential part of the extract was identified as the magnesium salt of ribonucleic acid, and we expressed the view that the dye-retaining material, that is, the 'Gram complex', was a magnesium ribonucleoprotein. This was eventually isolated from a number of Gram-positives by a short autolytic procedure and dissociated into Gram-negative magnesium ribonucleic acid and a Gram-negative basic protein which, if the —S—S— groups in the latter were kept intact, would re-combine to give a Gram-positive mass.

Further support came from various workers who showed that ribonucleases would destroy the Gram complex. Striking effects on Gram-positive cells can be obtained with reagents which have a strong affinity for ribonucleic acid. Lithium salts, for example, will cause the nucleic acids to aggregate into masses at the sides and ends of rod-shaped bacteria. Surface-active agents also cause the ribonucleic acid to clump initially and then to disappear. The significance of both magnesium and ribonucleic acid can be demonstrated with one organism, *Clostridium sporogenes*, a Gram-positive, which will grow in Gram-negative form under adverse cultural conditions such as magnesium starvation. Addition of magnesium salts will slowly restore the Gram-positive state, while addition of magnesium–ribonucleic acid will rapidly restore both living and dead organisms to the Gram-positive state.

In removing the surface layers of Gram-positives, many other macromolecules are removed, for example, polysaccharides, fats, phosphatides, etc.; but only ribonucleic acid will 'replate' in any measure. The replating can be seen in a striking manner by photographs in the ultra-violet, where the nucleic acids absorb. Dr. P. Mitchell, of Cambridge, has claimed that the essential part of the Gram complex is a '*P*' factor which is a phosphatide. In our hands, however, extraction, for example, of *Cl. welchii* cells, with boiling methanol and ether for several hours which would remove all Mitchell's factor, leaves 80 per cent of the cells Gram-positive. Phosphatides may help to absorb more of the dyestuff in the intact cell.

In true Gram-negatives, which have a significant ribonucleic acid content, and in Gram-negative cytoskeletons, the magnesium is all in ionic form; whereas in Gram-positives the major proportion of it is in co-ordinated form.

---

* Abridged from a paper entitled "Taking the Nucleic Acid Jackets off Bacteria" to Section B (Chemistry) of the British Association meeting at Bristol read on September 1.

Magnesium plays an important part in bacterial cell division and is an essential element for most Gram-positives, which require a higher proportion than do Gram-negatives. Since we have not been able to 'plate' magnesium ribonucleic acid on to true Gram-negatives, we consider that they possess proteins located near the surface which are in quite a different class from those in Gram-positives.

It has been possible, on the other hand, to use ribonucleic acid from Gram-negatives and from many other sources to 'replate' Gram-negative cytoskeletons, so that ribonucleic acid does not show any specificity in this type of interaction with protein. In no case could deoxyribonucleic acid be plated on to cytoskeletons. Recently we have made many efforts to obtain nucleic acids from yeast by means of mechanical disintegration of cells, and we have noted in such cases that the cytoskeletons cannot be restored to the Gram-positive state, neither can cytoskeletons be rendered Gram-negative by autolysis methods. The latter may be due to the very powerful and persistent action of ribonuclease, and only quite recently have we been able to isolate nucleoproteins from yeast free of this enzyme.

We have been able to discover that the useful antiseptic detergent, cetyltrimethyl ammonium bromide ('Cetavlon'), exerts its powerful action on micro-organisms by combining strongly with the surface ribonucleic acid. We have shown that there is a close association between the ribonucleic acid–protein surface components of the Gram complex and polysaccharide synthesis in some micro-organisms. This can be shown very well with those *Streptococci* which produce dextrans and lævans. It is possible that the ribonucleic acid of the Gram complex is part of the enzyme system, for while purifying dextrans and lævans and many other polysaccharides, ribonucleic acid can be shown invariably to be present as an impurity which is difficult to remove by fractionation methods.

The close association of nucleic acid with polysaccharide synthesis can be shown in a much more striking manner in the *Pneumococcus* group of bacteria, in which case deoxyribonucleic acid takes the vital role. Deoxyribonucleic acid 'jackets' in this group can be changed in a dramatic way, and when the jackets are changed we get a change of polysaccharide 'overcoat' also, for the deoxyribonucleic acid jackets and overcoats apparently have to match. The seventy types of pneumococci are detected by means of their serological reactions. Each type of *Pneumococcus* possesses a structurally different polysaccharide of high complexity, and running through the whole group is one common 'somatic' or group polysaccharide. Some of the structural differences between the specific polysaccharides are very profound, for example, as between types 1 and 3, while others have closely similar structures, for example, types 3 and 8.

In 1928 an Englishman, Griffiths, discovered the transformation of types whereby one type of *Pneumococcus* could be transformed into another thus :

Rough Type 1 live cells + Heat-killed encapsulated cells of smooth Type 2 → Type 2 live cells

also

Rough Type 2 live cells + Heat-killed smooth Type 1 → Type 1 live cells

also

Rough Type 2 live cells + Heat-killed smooth Type 3 → Type 3 live cells

Dawson and colleagues in the United States later confirmed these discoveries, and showed that any type could be transformed through its unencapsulated live form ; while Alloway, also in the United States, dissolved the heat-killed cells in sodium cholate and showed that extracts would still achieve the transformation of types. Then came the dramatic work of Avery and his colleagues in the Rockefeller Institute, showing that the factor achieving the transformation was deoxyribonucleic acid—a kind of type-specific deoxyribonucleic acid in each case.

A number of types have now been transformed with the appropriate highly purified deoxyribonucleic acid. The transformed cell takes on all the properties of the new type, including the property to reproduce the transforming deoxyribonucleic acid. Other bacterial types have also been transformed, and, in addition, other properties such as drug resistance have been transferred.

If we consider the mechanism of the biosynthesis of polysaccharides, we know that three components are required, namely, enzyme, substrate (a specific glucoside) and a primer. The latter must possess appropriate receptor groups and must be of the same pattern as the polymer to be synthesized, and it must possess a minimum number of sugar units in its chain.

According to these requirements, then, the transforming deoxyribonucleic acid could possess, and carry with it, its polysaccharide primer. Possibly a simple mono-layer would be sufficient, and it need be no larger than an oligosaccharide. In my view, it would mean that the so-called 'memory' of the transforming deoxyribonucleic acid is not solely due to its own structure, but is due in part to the specific carbohydrate structure holding it rigidly in shape until it meets, in the Rough form of an unencapsulated *Pneumococcus* cell, a receptive protein with which it can combine to re-form the complete enzyme system for polysaccharide synthesis. It is of interest to note what remarkable differences there are between the chemical structures of the *Pneumococcus*-specific polysaccharides, which are probably built up as 'block polymers'.

One of the great fields of investigation awaiting the attention of chemists is that involving the isolation and the chemistry of nucleoproteins. Determination of the mode of linkage between these two groups of natural molecule and their isolation in a form whereby biological function is retained will help in solving problems connected with the chemistry of living matter—especially with chromosomes, enzymes and viruses.

Our work has shown that their dissociation and recombination to retain 'living' attributes may not be too difficult a problem.

# RADIATION DAMAGE TO METALS AND ASSOCIATED PROBLEMS

N the course of the annual autumn meeting of the Institute of Metals, held this year in Buxton, a discussion was held on September 22 on the subject f "Radiation Damage in Metals". The Metal Physics Committee of the Institute had arranged this disussion under the chairmanship of Prof. R. W. K. Honeycombe, professor of physical metallurgy in the University of Sheffield, and speakers were drawn from the Metallurgy Division of the Atomic Energy Research Establishment.

Dr. M. J. Makin spoke about the effect of radiation on the mechanical properties of metals and the mportance of knowledge of this phenomenon when undertaking the building of nuclear reactors, much of the structure of which is inevitably exposed to a heavy flux of neutrons. An experiment in which the mechanical properties of nickel were tested before nd after irradiation showed, in respect of the rradiated sample, a considerable increase in yield stress, some reduction of ductility and a general ifting of the stress–strain curve. The rate of work-hardening was less in irradiated material than in the original. The mechanical properties of irradiated pecimens recorded at different testing temperatures showed that the results obtained were very dependent upon temperature, while a further variation in these properties was related to the temperature at which he irradiation took place. Some of the irradiation ffects can be annealed out. Experiments with copper show that 300–400° C. is a suitable range, orresponding to an activation energy of approximately 2 eV. With nickel, the range is 350–400° C., uggesting that the activation energy is about the ame as that of self-diffusion. The temperature indicated for nickel is rather lower than that at which cold work anneals out and, further, the eduction of ductility by irradiation is much less than hat brought about by cold work.

The effect produced by irradiation on mechanical properties appears to resemble more closely the change produced by the addition of an alloying element than, as had been suggested originally, that oduced by cold work. Irradiation of material with a ductile-brittle transformation raised the transition emperature. Work on single crystals of ductile metals shows that the rate of increase of yield stress s not linear; the effect appears to be proportional to the ½ power of the neutron dose, and there is no vidence of a saturation point. Efforts have been made to picture a mechanism involving the displacement of atoms by fast neutrons. Thus, Brinkman, discussing copper, has suggested that the knocked-on atom actually melts a very small region of the crystal and that solidification is so rapid that the atom will not return to its original position. Another uggestion is that the copper atoms knocked out of he lattice migrate in clusters, forming a pseudo-precipitate which is attached to dislocations.

Discussing techniques used in studying radiation damage, Mr. O. Plail said that the main divisions of his study—irradiation and subsequent examination—both call for special experimental techniques and cientific apparatus of novel types. It is necessary in he first place to avoid damage to the pile and, in he second, to carry out delicate tests by remote control on specimens which are strongly radioactive. Mr. Plail's contribution clearly demonstrated the demands now made on technicians and apparatus constructors and how well these demands have been met.

Dr. P. C. L. Pfeil dealt particularly with the preparation and microscopic examination of irradiated specimens. The microscope used is of the usual inverted type, but the optical system following the objective is replaced by a high-definition television camera. The camera is connected to a large monitor-tube mounted in a conventional cabinet, and the image of the specimen is displayed on this monitor. A very high standard of resolution has been attained, photographs of the screen image (magnification, × 1,000) being remarkably clear. Dr. Pfeil discussed the microstructures revealed by such examination and mentioned that a Russian delegate at the Geneva Conference reported that a sample of alloy containing alpha-uranium and gamma-uranium became 100 per cent gamma-phase when irradiated at a temperature at which it would otherwise have remained two-phase. There is a difference of opinion as to the mechanism involved in this change, but Dr. Pfeil favours the view that the presence of a body-centred-cubic nucleating agent will initiate the growth of a small region of body-centred-cubic structure among atoms which are cooling after the intense local heating in the track of a particle.

Dr. H. M. Finniston, head of the Metallurgy Division of the Atomic Energy Research Establishment, spoke about radiation damage in uranium and the marked dimensional changes observed in irradiated specimens. It has been found possible to study the dimensional changes by using a thermal analogy, and, although the phenomena are entirely different, the analogue method has given valuable information. It centres around the alpha–beta change which occurs at 650° C. and consists of repeated thermal cycling between 600 and 650° C. When this method was applied to rod specimens prepared in different ways, some specimens bent, and others grew lengthwise or suffered severe surface wrinkling. These effects can be explained by considering how the different fabrication processes or treatments have affected crystal orientation in the rods, since uranium shows pronounced crystal anisotropy. The closeness of the analogy is demonstrated by the effect of pile irradiation on single-crystal specimens of uranium which grow in the direction of the preferred axis. Dr. Finniston discussed the possible forms in which nuclear fuel might be prepared in future. He also referred to the difficulties of studying the properties of plutonium, which has six phase changes against the three in uranium.

Dr. J. H. O. Varley discussed radiation damage in ionic solids with particular reference to the alkali halides and methods of evaluating σ, the ionization cross-section. The investigating tool used is the colouring of the halide crystals on irradiation[1,2]. The colouring can be partly bleached out by light and more thoroughly by heat. The 'temporary' colouring (bleached by light) corresponds to displacements of electrons in the lattice, and the 'permanent' colouring (fast to light) is associated with displacement of atoms. The measured cross-section determined from the number of permanent colour centres per c.c.

produced by a given bombardment is of the order $3 \times 10^{-21}$ cm.$^2$. The cross-section calculated on the assumption that displacements are produced by direct collision with atomic nuclei lies between $5 \times 10^{-23}$ and $10^{-22}$ cm.$^2$. The measured cross-section gives a lower limit to the value pertaining to the principal displacement mechanism because there is not necessarily a one–one correspondence between the number of displacements and the number of colour centres produced. Dr. Varley used the relation between the cross-section $\sigma_p$ for a $p$-fold ionization of a given atom or ion and the cross-section $\sigma_1$ for a single ionization in the approximate formula

$$\sigma_p \sim \sigma_1 \left(\frac{\sigma_1}{A}\right)^{p-1}$$

where $A$ is the 'area' of the atom. From the range–energy relation obtained experimentally, it appears that $\sigma_1$ is of the order $10^{-17}$ cm.$^2$; $A$ can be taken as $\sim 10^{-15}$ cm.$^2$. By the substitution

$$\sigma_p \sim 10^{-17}(10^{-2})^{p-1}$$

since $\sigma_p \sim 10^{-21}$ cm.$^2$, the approximation gives $p = 3$ as the number of electrons stripped from one ion. It is thus indicated that the removal of three electrons from a given negative ion is a sufficiently probable process to account for the number of colour centres and, consequently, for displacements produced, if it be assumed that each one of these three-fold ionized ions is ejected from its lattice site and trapped at some other site in the crystal. The end-state can thus be halogen atoms in interstitial positions, trapped in positive-ion vacancies or at dislocations, and electrons trapped in the sites vacated by the halogen ions, these electrons giving rise to the colour centres. Dr. Varley concluded by remarking that vacancy pairs can lead to fast bleaching by acting as scavengers, but there is still much to be elucidated.

# THE NATIONAL GEOGRAPHIC SOCIETY—PALOMAR OBSERVATORY SKY ATLAS

THE first section of the Palomar Sky Atlas has recently been distributed to subscribers. This Atlas is being prepared from a survey of the sky north of declination −27°, made with the 48-inch Schmidt telescope on Mount Palomar. This area of the sky has been photographed on 879 pairs of plates; each plate of size 14 in. × 14 in. covers an area of 7 × 7 degrees. The plate centres are separated by 6°, so that adjacent plates overlap by ½ degree.

Each field is photographed in two colours in immediate succession. The blue exposures are obtained on the Eastman 103*a*0 emulsion, with a wave-length range of from 3500 A. (the short-wave transmission limit of the correcting plate) to 5000 A., the maximum sensitivity being at about 4100 A. The red exposures are obtained on the Eastman 103*aE* emulsion, combined with a red 'Plexiglass' filter, with a wave-length range of from 6200 A. (the short-wave cut-off limit of the filter) to 6700 A., the maximum sensitivity being at about 6500 A.

The exposure times for each series were chosen to reach the faintest stars which can be recorded by the telescope under average observing conditions. These times were separately determined for each shipment of plates and range from 10 to 15 min. for the blue exposures and from 40 to 60 min. for the red. The photographic magnitude limit is 21·1 for the blue plates and 20·0 for the red. The magnitudes of stellar images on the blue plates are approximately on the same system as that of the international photographic magnitudes, and those of the images on the red plates are approximately on the same system as the red magnitudes of Kron and Smith. The differences between blue and red magnitudes of stars on the survey plates are approximately 1·6 times their international colour indices. Stars having an international colour index of 0·7 appear about equally bright on the blue and red plates. The scale of the plates is 67·1 seconds of arc per millimetre.

Each pair of photographs of a field was inspected for quality before being accepted for reproduction in the atlas. If one member of a pair was rejected, the area was re-photographed in both colours. Many fields had to be photographed several times before both plates were passed as acceptable.

The photographs were first reproduced as positive transparencies. The photographic prints are in the form of negative reproductions, because they alone permit of satisfactory preservation of the plate limit. The prints were made by the Graphic Arts Facilities of the California Institute of Technology. Care has been taken to ensure that the faintest details at the limits of the plates are reproduced even at the price of inadequate reproduction of bright objects, so that the images of faint stars, galaxies and nebulosities, which are beyond the reach of smaller instruments, are preserved.

After extensive tests and trials, Eastman Kodak Finegrain Positive glass plates were selected for the positive transparencies and Eastman Kodak Unicontrast double-weight paper for the negative prints. The contrast of the paper is gamma 2·0, practically independent of development. The original plates show considerable variation in background density, which depends upon the sky brightness. Original plates with background densities less than 0·3 and greater than 0·9 were found to give inferior results and were rejected. The most satisfactory reproduction was found to be obtained by printing all positives to a density of 1·4. The paper prints were found to be most satisfactory with a density of 0·2 or slightly higher.

On the back of each print is stamped the nominal position of the plate centre for epoch 1855. In the north-east corner of each photograph is a label giving the serial number of the plate, the date of the exposure and the 1950 co-ordinates of the field centre.

The survey was made financially possible by generous grants from the National Geographic Society, which provided the photographic materials and equipment, the salaries of the personnel employed on the survey, and the cost of producing two contact positives on glass of each survey photograph. The bserving time with the 48-inch Schmidt telescope required to obtain the survey photographs was made available by the Palomar Observatory of the California Institute of Technology. Approximately ight years of observing time (1949–56) will be equired to obtain the negatives. The copyright for the Atlas is held by the National Geographic Society.

The Atlas has been made available at a price that overs only the cost of production and handling of he prints. The estimated cost was 2,000 dollars per set of 1,758 prints (879 blue exposures and 879 red exposures) if fifty copies were ordered and ,600 dollars per set if a hundred copies were ordered. The actual price can only be established after the printing is completed. Cancellation of orders will be accepted if the estimated price is higher than ,000 dollars. Only one printing of the Atlas is planned, and no orders could be accepted after October 1, 1954, when the reproduction was commenced.

The Atlas will provide an invaluable working tool for observatories that possess copies. The Franklin Adams Charts, which covered the whole sky but which were made from originals on blue-sensitive emulsions only and which did not reach nearly to such a faint magnitude as the Palomar survey, have for many years proved of great value for many purposes. The photographs in two colours of the present survey and the faint-magnitude limit reached are of special importance: it is readily possible, for example, to recognize red stars and blue stars by the comparison of the sizes of their images on the blue and red photographs, while for such studies as those of interstellar absorption and the distribution of faint galaxies the reproductions will prove most useful.

It is recommended that, in order to prevent damaging the prints when in use, they should be covered with glass plates. The most satisfactory illumination is with the light source low and to the rear.

In making this Atlas available and at a reasonable price, astronomy will owe a great debt to the National Geographic Society and to the Mount Palomar Observatory.

H. SPENCER JONES

# OBITUARIES

## Prof. A. R. Radcliffe-Brown

WITH the death on October 24 at the age of seventy-four of Prof. Alfred Reginald Radcliffe-Brown, emeritus professor in the University of Oxford, comparative social anthropology has lost its leader and foremost exponent. An intellectual heir of Montesquieu, Comte and Spencer, he represented the theoretical tradition which culminated in Durkheim, flourished with the French sociological school and was submitted to the test of empirical field-observations by British anthropology.

Radcliffe-Brown read mental and moral science as a scholar of Trinity College, Cambridge, and he worked with both Rivers and Haddon. At the age of twenty-six, after his election to the Antony Wilkin studentship in ethnology, he carried out research among the Andaman Islanders. His book under that title, completed in 1913 and published in 1922, is a brilliant analysis of ritual and of social organization. Together with the account of the Cambridge expedition to the Torres Straits and with Malinowski's "Argonauts of the Western Pacific", it inaugurated a new departure and pointed the way to the intensive field-work characteristic of modern anthropology. Apart from a number of important articles, this pioneering work marked Radcliffe-Brown's principal contribution to the field-study of primitive peoples. This was due mainly to his conception of social anthropology as a natural science of society and, within this discipline, to his personal attraction to inquiries aiming at the establishment of general principles.

Radcliffe-Brown propagated his views with zeal, and this left him with little time for field-investigations. He was appointed the first professor of social anthropology in the University of Cape Town (1921), head of the newly created Department at Sydney (1926), where he founded and edited *Oceania*, and professor at Chicago in 1931. Between 1937 and 1946 he occupied the newly created chair at Oxford, where he was a Fellow of All Souls, which had taken a leading part in its establishment. He also taught social anthropology at Cambridge, London, Birmingham, Pretoria, Johannesburg, Yenching, São Paulo, Alexandria, Manchester and Grahamstown.

A man of distinctive appearance, he combined a natural charm of manner, kindness to his colleagues and generosity to his juniors with an innate reserve which, at times, bordered on aloofness. He was happiest and most relaxed in the social climate of a 'salon', where he could discuss with equal verve an exotic recipe or his personal conception of Confucian philosophy.

Radcliffe-Brown was by temperament, method and necessity a thinker rather than an observer, a conversationalist, lecturer and essayist rather than the writer of lengthy treatises. He wrote with *litotes* and crystalline clarity, and his essays on kinship, taboo, primitive law and social structure have proved invaluable in helping to lay the anthropological foundations of the subject; and they are indispensable in its present-day teaching.

J. G. PERISTIANY

## Dr. G. Placzek

DR. GEORGE PLACZEK, of the Institute of Advanced Study, Princeton, who died at Zurich on October 16, was born in 1905 in Brunn (now Brno, Czechoslovakia). After studying theoretical physics in Vienna and Prague, he moved around Europe, working in Utrecht, Leipzig, Copenhagen and Paris, among other places. He spent a year at the Hebrew University, Jerusalem. In 1938 he went to Cornell University, and later worked on atomic energy at Cambridge, Montreal and Los Alamos. After two years in the research laboratory of the General Electric Company at Schenectady, he joined the Institute for Advanced Study in Princeton in 1948. He married in 1943.

Placzek's earliest major work was on the theory of the Raman effect, on which his review article became a classic. This led to a study of molecular rotational states, then a fruitful tool for determining nuclear spins. Later he turned to neutron problems. With O. R. Frisch he first proved that resonance-levels for neutron capture have extremely low energies. In collaboration with others, he helped to clarify the dispersion formula for nuclear reactions. Then came a study of the slowing-down of neutrons, which was started for its intrinsic interest, but proved of great importance for work on atomic energy. This led to study of the integral equations of neutron multiplication summed up recently in a book he wrote with K. M. Case and F. de Hoffmann. Since the end of the Second World War, his main interest has been in the scattering of neutrons by solids and liquids, which is important both for its contribution to neutron physics (it made possible the interpretation of experiments on neutron–electron interaction) and for its application to the study of solid state.

In each field his work was characterized by a penetrating thoroughness. He would not leave a problem so long as there was an important difficulty unsolved or a major relation not thought out. He always used simple techniques where possible, and usually used symmetry principles and classical laws for results where others might have tried much more elaborate methods.

His standards were high, and he had no patience with slipshod arguments either in his own work or in that of others. He did not suffer fools gladly, and this is probably why he had no enthusiasm for teaching, and had only a few pupils. But to those, and to others on his own level, discussions with him were always inspiring.

But what will be remembered of Placzek above all was his personal charm, his width of intense interest and his erudition, his understanding of people, and his integrity. He would have no more patience with slackness of moral principles than with sloppy mathematics, and he would not pay attention to the effect his principles would have on his personal convenience.

In his later years he was much troubled with ill-health, and for much of the time he would not have been able to keep his work going but for his iron determination, and for the care, and the vitality, of his wife.

R. E. PEIERLS

# NEWS and VIEWS

## British Cotton Industry Research Association: Dr. F. C. Toy, C.B.E.

The Council of the British Cotton Industry Research Association has announced that Dr. F. C. Toy will be retiring from his position as director of research at the end of this year. He was first appointed in 1944, having previously served for thirteen years as deputy director under the late Sir Robert Pickard. During his directorship, the Shirley Institute has expanded considerably to meet the increasing and changing demands of the industry it serves, and it is due largely to his wise and able direction that, by the quality and value of its work, the Institute is now generally recognized in industrial and scientific circles alike as the leading textile research association in the world. Although the main feature of the advances made under his influence has been the wider appreciation and utilization in the Lancashire textile industry of the practical results of research, he has remained true to his conviction that technological advances must ultimately be based on fundamental research, and he has ensured that a steady flow of such work has been maintained. This is reflected in the fact that the scientific standing of the Institute was never higher than it is to-day. Dr. Toy has the gift of stimulating interest and enlisting the support not only of those working under him, but also of those with whom he comes in contact, and it is not surprising, therefore, that he has won the respect of his staff, and of men at all levels in the Lancashire industry. The national importance of his work was recognized by the award of the C.B.E. in 1947.

The heavy responsibilities of his office have not lessened Dr. Toy's interest in his own subject of physics, and throughout his career he has taken an active part in the affairs of the Institute of Physics, culminating in his appointment as president for the period 1948–50. He has also taken a leading part in the activities of the well-known Manchester Statistical Society, of which he was the president during 1951–53. Although Dr. Toy leaves the Institute to the care of a younger man, he himself is undiminished in vigour of mind and body, and while one sympathizes with his desire to relax a little, one hopes that the great services he is yet able to render both science and industry will not be lost to the country.

## Dr. D. W. Hill

Dr. D. W. Hill, who succeeds Dr. Toy as director of the British Cotton Industry Research Association, joined the staff of the Shirley Institute in 1937 and was appointed deputy director in 1944; and it is a source of pleasure to the industry and to the staff of the Institute that he will be able to continue and extend the work which he has shared with the director for the past twelve years. Dr. Hill was born in Bristol, and is a chemist by training, having graduated from the University of Bristol with first-class honours in chemistry in 1924. After academic work in Liverpool and three years in the research laboratories of Messrs. Boots Pure Drug Co., Nottingham, he spent three years with a Commonwealth Fund Fellowship first at the University of Illinois and then at the Rockefeller Institute. Then came a year in the University of Bonn, followed by two years as special lecturer in chemistry in the Universities of Bristol and Exeter.

With this background of academic and industrial research, Dr. Hill was appointed to an administrative position at the Shirley Institute in 1937; but in 1940 was seconded to the Cotton Control, working in Manchester and London, and also for a time in the United States. He returned to the Shirley Institute in 1944 as deputy director. Dr. Hill's two books, "The Impact and Value of Science" (1944) and "Co-operative Research in Industry" (1946), are well known, and prove his complete faith in the value of co-operative research as it has been developed in Britain. He is fully convinced of the need for the carrying out of fundamental research by a research association serving what is still largely a craft industry, but is also very conscious of the need to apply the results of such research as quickly as possible to the special requirements of that industry. These are difficult times in Lancashire, but it is Dr. Hill's conviction that the greater the difficulties the better the opportunity for proving the value of scientific and technological research.

## Thomas Graham (1805–69)

Thomas Graham, whose discoveries in chemistry and physics had far-reaching effects on modern physiology, was born at Glasgow one hundred and fifty years ago on December 20, 1805. He studied chemistry at the University of Glasgow under Thomas Thomson, graduated M.A. in 1824, and in 1830 became professor of chemistry at the Andersonian College. In 1837 he was appointed to the chair of chemistry at University College, London, and in 1855 he succeeded Sir John Herschel as Master of the Mint. Graham's name is attached to a tube plugged at one end with plaster of paris, which he used in his experiments on the molecular diffusion of gases (1829–31), and to his famous law. Separating animal and other fluids by dialysis, he distinguished between colloids and crystalloids; he also established the polybasic nature of phosphoric acid and noted the formation with alcohol of certain salts, which he called alcoates and which he observed to be analogous to hydrates. Graham possessed a lively mind, though his body was feeble, and he led a full and busy life. He was vice-president of the chemical jury at the Great Exhibition of 1851 and assisted in various inquiries ranging from the ventilation in the House of Commons and London's water supply to methods of gun-casting. At the age of thirty-one he was elected a Fellow of the Royal Society and was awarded Royal Medals in 1838 and 1850. In 1840 he became the first president of the Chemical Society, which he had helped to found, and six years later first president of the Cavendish Society. His "Elements of Chemistry" (1842) was long a classic. Graham died on September 11, 1869, at the age of sixty-four.

## Gregor Johann Mendel

Prof. E. O. Dodson, of the University of Notre Dame, United States, has been fortunate enough to obtain a transcript of material on the life and work of Mendel taken from the archives of Mendel's monastery and of the Augustinian Order in Rome. The material was collected during the 1930's under the direction of the Right Rev. F. W. Howard, Bishop of Covington, Kentucky, and was entrusted by him to Sister M. Julitta, of Villa Madonna College (*Scientific Monthly*, 81, No. 4; October 1955). Using this material, Prof. Dodson has compiled a fascinating account of Mendel's early life and education, his training and monastic work in the monastery of Brunn, his election as abbot, and his unswerving endeavours to discover natural laws. The article also throws new light on the rediscovery of Mendel's work by de Vries, Correns and von Tschermak.

## Noise, Vibration and Health

In the House of Commons on December 2, Sir Lionel Heald introduced a debate on the effect of noise and vibration on the health, well-being and efficiency of the nation, and urged the Government to give careful attention to research and education in this field, and to the need for more effective measures for the protection of the public. Tribute was paid by Sir Lionel, and by other speakers, to the immense amount of work which has been done in this field by the Building Research Station, and, on the medical side, by Dr. Littler and others at King's College Hospital; but it was urged that full advantage is not being taken of available knowledge. Mr. R. Bell, in seconding the motion, besides directing attention to the scope for administrative action and the need for some amendment of the law, suggested that Ministers responsible for departments which are the main offenders should insist on departmental programmes of research and education, and in particular urged that the definition of noise should replace vague terms such as 'reasonable and practicable'. Replying for the Government, the Joint Under-Secretary of State for the Home Department, Sir Hugh Lucas-Tooth, agreed that responsibility must rest with individual departments, and he advised the House to accept the motion. The control of exhaust noise from motor-vehicles is partly in the hands of the police, with whom man-power is a major difficulty, and partly a technical problem between the Ministry and the manufacturers. As regards aircraft, a new principle embodied in the Conway engine is claimed to effect a further reduction in noise, and in the view of the Minister of Supply, technical effort in this field should be directed to the problem in connexion with new types of aircraft. Sir Hugh also referred to the study of vibration caused by passing aircraft, undertaken by the Building Research Station, to the attention being given to the prevention of noise in hospitals and to the investigations of the effect of noise in factories made by the Industrial Health Research Board.

## Thermonuclear Explosions

Following the broadcast from Moscow reported in the press that Soviet Russia is willing to discontinue hydrogen bomb tests by common agreement, the Government has been repeatedly questioned in the House of Commons on the subject. On November 30, in reply to Mr. Attlee, the Prime Minister stated that the Government had had no communication on the subject from the Soviet Government, but was ready to discuss these matters at any time. Sir Anthony commented that the reported statement might have appeared in a better light if it had been made before the recent Soviet explosion, and added that in any such discussions regard would have to be paid to the number and nature of the tests which each country had already made, as well as to those proposed. He also said that it remained the view of the British Government that a comprehensive disarmament agreement is the only final solution to these problems. When pressed by Mr. Attlee on that day, the Prime Minister did not, however, deal with the fundamental reason causing concern over the continuance of such tests, namely, the possible biological effects of the resultant radiation, or with the fact that no system of inspection is necessary to ensure that thermonuclear tests are not made in spite of undertaking to discontinue them, because such explosions can be detected over a wide area. These points were raised on December 1 in a question asking the Prime Minister to propose to President Eisenhower and Marshal Bulganin a cessation of all nuclear explosions pending the report of the United Nations Commission which is considering the effects of radiation. There was also on the notice paper a motion regretting the continuance of such tests, and expressing the belief that the tests in themselves involve a danger to the human race and requesting the Government not to proceed with such tests. On December 6, in reply to further questions, the Prime Minister suggested that we should await the report on nuclear radiation from the Medical Research Council, which is expected within two or three months, and also one from the United States National Academy of Sciences. He also said that the Government has no intention of departing from its decision to manufacture the hydrogen bomb, and it still regards manufacture and possession of the hydrogen bomb as a deterrent to war. While willing to discuss methods of regulating and limiting test explosions which take account of our position as well as that of other countries, the Government is not prepared to accept agreements which would put the United Kingdom in a position of decisive inferiority to other great Powers and one not justified by our scientific knowledge and resources.

## Gift to the University of Leeds for a Research Institute of African Geology

THE Anglo-American Corporation of South Africa, Ltd., has recently given £100,000 to the University of Leeds for the foundation of a Research Institute of African Geology under the direction of Prof. W. Q. Kennedy. The Research Institute will be an integral part of the Department of Geology, of which Prof. Kennedy is head, and will have as its primary objects fundamental research into the origin of mineral deposits generally and the study of African geological structure in particular, and the training of postgraduate research geologists by means of active field-work in connexion with problems of African geology. Both research fellows and post-graduate research students will work on the complex problems of rock constitution, tectonics and mineral distribution in various parts of Africa. The field sessions in Africa will alternate with periods of laboratory work in Leeds, where the Department of Geology is already well equipped to undertake such work and where an additional building now being converted for use by the Department will help to house the Research Institute. By this means it is hoped to gather information both on the interpretation of continental structure and the determination of the factors which control the distribution of minerals of economic value. Prof. Kennedy has been concerned for some years with geological problems in various parts of Africa, and during 1951 and 1952 led expeditions to Mount Ruwenzori (16,794 ft.) on the border of Uganda and the Belgian Congo. These expeditions, which included members of the Colonial Geological Survey, the British Museum (Natural History) and the University of Leeds, have resulted in a new interpretation of the structure of that area.

## Mining, Geological and Metallurgical Institute of India

NEXT January, the Mining, Geological and Metallurgical Institute of India will celebrate its golden jubilee. At the turn of the century, the need for scientific development and utilization of the mineral wealth already discovered in India by geologists was beginning to be realized by the pioneers in the field of mineral industry. At that time, there was no technical association in the country specifically devoted to the promotion of study and research in geology, mining and metallurgy. Conscious of the need for such an organization, and one that would also safeguard the interests of the industries and personnel concerned, a number of leading mining engineers, geologists and industrialists founded the Institute in January 1906. From its inception the Institute has played a part of ever-increasing importance in guiding and developing the technical advances pertaining to geology, mining and metallurgy in India. To celebrate the fiftieth anniversary, the Institute has arranged for an exhibition of modern mining and metallurgical equipment and a programme of visits to coal, manganese-ore, iron-ore, mica, and oil fields, manufacturing and industrial centres, and dam sites. These will be held in January immediately after th Industries Fair at Delhi, and just before the meeting of the Indian Science Congress at Agra. The Institut will welcome members of the mining, geological metallurgical and allied engineering professions, an of learned societies and related technical organizations in other parts of the world. Further informatio can be obtained from the headquarters of th Institute at 27 Chowringhee, Calcutta 13.

## Indian Council of Ecological Research

FOLLOWING a resolution made by the Governmen of India, the Indian Council of Ecological Researc has been founded. Its main objectives will be t study Indian vegetation with the view of collectin basic data on desert and flood control, forestry, soi conservation, agriculture, wild-life management nature conservancy and pasture management. Th founder-chairman of the Council is Shri C. R Ranganathan, inspector-general of forests to th Government of India. The Council has recentl published the first number of its *Bulletin* (1, No. 1 October 1955. Indian Council of Ecological Research New Forest, Dehra Dun). This number contains statement on the vegetation types of India issued a the symposium organized by the Indian Botanica Society held at Baroda during January 1–2, 1955 which led up to the Government's resolution. Th terms of reference of the new Council are also included, together with a personal note on its founder chairman. G. S. Puri, secretary of the Council, contributes a paper on the aims and objectives o ecology, and there are two short papers by Prof W. H. Pearsall (London) and E. H. Graham (Washington).

## Comets and Climatic Changes

IN a paper entitled "Évidences Cométaires de Variations des Climats" (*Bull. Astro. Inst. Czechoslovakia*, 6, No. 1; 1955), F. Link and Z. Linkov deal with statistical research relating to the discover of comets, correlated with solar activity. They hav found that the annual number of comets discovere varies in the course of the solar cycle of eleven years This variation is inversely proportional to rainfall with two maxima during the eleven years, accordin to Helman's investigations, and more recently it ha been found that the number of comets discovere during a cycle is greater in the even than in the od cycles. The numbers of comets discovered betwee 1755 and 1953 are arranged in cycles 1–18, and the the mean number of discoveries per year in th successive cycles is given separately for even and odd cycles. The influence of the meteorological conditions on the observations of comets is shown by means of a graph. Solar activity being greater durin the odd cycles, the circulation in the terrestrial atmosphere is increased, and in consequence observations become more difficult; as a result of this, ther is a decrease in the number of comets observed.

This close connexion between the number of comet discovered and the meteorological conditions (th latter depending on solar activity) led the authors t carry out investigations on climatic variations sinc 1611, and the principle underlying this research i based on the assumption that the number of comet discovered is a function of three factors: the cosmi factor, that is, the actual number of comets tha approached the Earth; the climatic factor, or th atmospheric conditions in civilized countries, whic only need be included, as observations of comets i uncivilized countries would be useless for statistical purposes; the social factor or human activity (in particular, astronomical activity) in civilized countries. While the first factor can be regarded as constant, the second would increase in a more-or-less continuous manner in time, and the third would be revealed in the slope of the curve $N = f(A)$, $N$ being the number of comets discovered from zero year up to the year $A$. Both these quantities have been taken from a catalogue by Baldet ("Ann. Bur. Long", Supp. 1950), and a searching analysis of the results leads to certain conclusions on the meteorological conditions between the years 600 B.C.–A.D. 1740. A comparison is made between these and the data given by C. E. P. Brooks in "Climate through the Ages", covering about a thousand years up to comparatively recent times, and there is a close accordance between them. The Czechoslovak workers hope to carry out further investigations on the subject.

### Imperial Forestry Institute, Oxford: Report for 1953–54

In an introduction to the thirtieth annual report of the Imperial Forestry Institute, Oxford, for 1953–54 (pp. 29; 1955) there is a good résumé of the work of the year. The number of students, particularly in the graduating class and in the research group, naturally varies from year to year; it was below normal during the year under review, but the report states that there would be an increase in the following year. A noteworthy feature of 1953–54 was that practically none of the new graduates sought employment either with the Forestry Commission or in the Colonial Forestry Service. They showed a preference for careers in private enterprises in Britain or Canada. Forestry employment in many of the Colonies is in such an uncertain position that the preference for a safe job is not surprising, though rather sad. Forestry probationers from overseas still go to the Institute; of the ten men who obtained the forestry degree, one was a Colonial forest probationer and returned to his Colony, one was a New Zealand forest scholar and has returned home, and two have gone back to Canada. Sixteen officers of the Colonial Service attended the forest officers' course, coming from Nigeria, Tanganyika, Northern Rhodesia, Sierra Leone, Kenya, Uganda, North Borneo and Fiji. The special Indian course has not yet grown to maturity; but two forest officers attended it, one from India (Bengal) and one from Pakistan (Punjab). The practical courses on the Continent have increased both in number and variety, and are arranged for the varying types of students attending the Institute. The work of the different branches of the Institute is discussed, and the report as a whole furnishes evidence of the value of the Institute to British forestry in its widest sense.

### Crystallographic Symposia in Madrid

The International Union of Crystallography is holding a symposium in Madrid during April 2–7, 1956, on "Structure on a Scale between the Atomic and the Microscopic Dimensions". As well as the symposium, the Union is organizing an open meeting of the Commission on Crystallographic Apparatus and also a series of meetings on crystallographic teaching during April 3–6. Details of the programme will be published in *Acta Crystallographica*; but the main topics are: analysis of material from a world-wide survey; apparatus and books for teaching crystallography; and the teaching of crystal physics, crystal geometry, structure analysis, mathematical techniques and machines. Short papers for circulation prior to the meeting should be submitted by February 1, all communications being sent to the secretary, Dr. H. Judith Grenville-Wells, Chemistry Department, University College, Gower Street, London, W.C.1. Those who wish to submit papers should send the titles and abstracts by January 1 to the chairman of the Programme Committee, Prof. A. Guinier, Conservatoire National des Arts et Métiers, 292 rue Saint-Martin, Paris 3e. Further information on the symposium can be obtained from the Secretario del Comité del Symposium de la Union Internationale de Cristallographie, Instituto de Fisica, Serrano 119, Madrid.

### Animal and Human Diseases in East Africa: Conference in Kampala

The East African Medical Research Scientific Advisory Committee will be holding a "Zoonoses Conference" in Uganda at Makerere College, Kampala, during January 11–13, under the presidency of Mr. H. Binns, director of the East African Veterinary Research Organization, Muguga, Kenya. The first day will be devoted to the general pattern of both human and animal diseases in East Africa and their relation to the fauna, particular attention being paid to kala azar, plague, relapsing fever, rabies and Q fever. During the following two days there will be four symposia at which will be considered brucellosis, helminthiasis, viruses and trypanosomiasis, respectively. The conference secretary is Prof. J. N. P. Davies, Pathology Department, Makerere College Medical School, P.O. Box 2072, Kampala, Uganda, to whom all correspondence should be addressed.

### Announcements

The Chemical Society is offering a Corday–Morgan Medal for 1954 which, together with a prize of 200 guineas, is open to persons of British nationality, less than thirty-six years old, for published work in experimental chemistry. Applications or recommendations for the award should be made before December 31 to the Chemical Society, Burlington House, London, W.1.

The Radio Industrial Council is again offering this year up to six premiums of 25 guineas for articles which are likely to enhance the reputation of Great Britain in radio, television and electronics. Articles published in journals circulating exclusively to members of a trade or in privately published journals of professional institutions or learned societies will not be eligible. In addition, the author must not be engaged full-time in technical writing. Entries, which must include five copies of the article concerned, should be sent before December 31 to the Secretary, Radio Industry Council, 59 Russell Square, London, W.C.1.

A series of natural-history lectures and films for junior audiences, 10–16 years of age, will be given at the British Museum (Natural History), South Kensington, London, S.W.7, during the Christmas holidays, starting on December 27 and continuing each day until January 7, Sundays excepted. The lectures will be free and without booking. Programmes are available on application to the inquiries desk or on written application to the guide lecturer at the Museum.

# LONDON RESEARCH STATION OF THE GAS COUNCIL

## OPENING OF NEW LABORATORIES

On November 18, Sir Robert Robinson formally opened new laboratory buildings at the Fulham works of the North Thames Gas Board which provide additional accommodation for pilot plant and chemical engineering experimental work. Together with the older buildings, these laboratories now constitute the Fulham Laboratories of the Gas Council's London Research Station.

Prior to the nationalization of the gas industry in 1949, there existed two main research establishments in Britain concerned with the production and use of gaseous fuels. These were the research department of the Gas Light and Coke Company started in 1924, and the Gas Research Board, which was set up in association with the Department of Scientific and Industrial Research in 1939. After vesting day, the Gas Council assumed responsibility for research in the industry, and it was decided to keep the former Gas Light and Coke Company's laboratories at Fulham in action as the London Research Station, and to set up a new research station in the Midlands to replace the Gas Research Board.

The London Research Station now consists of two groups of laboratories. Those situated at Fulham gas works are concerned with the manufacture and purification of gas, and with the recovery of by-products. Those at Watson House, on a site adjoining the works, are devoted to the use of gas in appliances of all kinds. The station is operated by the North Thames Gas Board on behalf of the Gas Council.

The laboratories at Fulham were originally opened in 1928 and at the end of the War had expanded into some temporary buildings which were used largely for pilot-plant experiments. The new buildings provide proper accommodation and facilities for this type of work. It is thus possible to carry out a research programme which covers a suitable range of small-scale, analytical and pilot-plant experiments together with design work in the chemical engineering field. Most of the new space is occupied by three large laboratories intended for pilot plants of small and medium size and for work in connexion with full-scale tests on plant in actual operation at any of the works of the North Thames Board. In addition, there are offices, lobbies, workshops and stores.

The older buildings, which were also open to inspection by visitors on November 18, contain four large laboratories which are devoted respectively to physical chemistry, to analytical operations, to by-products chemistry, and to problems arising from the construction and maintenance of gas-making plant. There are also offices, workshops, stores, several small laboratories for special purposes such as X-ray equipment or spectrographs, and a library.

The London Research Station is fortunate in that it can make full use of the extensive engineering, stores and workshop facilities of the Board. It is also customary for large pilot-plants to be installed at one or other of the Board's twenty-one gas-making works.

The overall programme of research authorized by the Gas Council is shared mainly between the London Research Station and the Midlands Research Station at Solihull; but work is also carried out in the laboratories of the South Eastern Gas Board, by the Fuel Department of the University of Leeds, and by other research associations to which the Gas Council subscribes. This programme falls into eleven main sections, concerned respectively with the manufacture of coal gas, the production of water gas and oil gas the cooling and washing of gases, the removal of sulphur compounds, the recovery of by-products, the construction and maintenance of gas-making plant flame and combustion, domestic and industrial heat services, ventilation and flues, refrigeration, and the provision and use of solid smokeless fuels.

Owing to the growing shortage and increased cost of good gas-making coals, some of the most important problems concern the production of gaseous fuels from low-grade coals and oils. Experiments on these problems were not on view at Fulham as they have reached the stage where the pilot plants have to be installed on a works site, or where the work is being done at the Midlands Station.

Among the items which were seen during the tour of the Fulham laboratories, particular interest is attached to four, which are concerned with the biological oxidation of aqueous effluents, the removal of sulphur compounds from gaseous fuels, the search for improved refractory materials, and studies in mass-transfer and heat-transfer processes.

During the purification of gases produced from coal, aqueous condensates are always obtained in association with tar. These liquors contain valuable substances such as ammonia and phenol, which are largely recovered; but small quantities of impurities always remain to make the final effluent harmful to vegetable or animal life in rivers or streams. In order to destroy the traces of phenols and ammonium thiocyanate which are present in these liquors, biological treatment, apart from disposal in sewage treatment plant, is being investigated and a considerable degree of success has already been reached in the search for suitable cultures.

Crude fuel gases always contain sulphur compounds, notably in the form of hydrogen sulphide, and efforts are being made to replace the conventional dry-box purifier which is used for its removal by a process depending on liquid reagents. Any success in this direction might also involve the production of elemental sulphur by a catalytic process, and an investigation into the physical properties of catalysts is associated with this section of the programme. Interest in catalysts is also extended to those used for the decomposition of organic sulphur compounds in gases.

The carbonization of coal in continuous vertical retorts is a process with a high thermal efficiency and several other attractive features; but conditions in the retorts are so severe that the life of the refractory materials used in their construction is relatively short. Much of the damage arises at the time when carbon deposits are burned off the brickwork at intervals, and a search is being made for refractory materials which will resist this disruptive action. As a contribution to this search, the mechanism of the deposition of carbon and of its removal by combustion is being investigated in high-temperature experimental furnaces.

Many processes in the gas industry involve mass and heat transfer. For example, the cooling of gas is a process of heat transfer with simultaneous mass transfer of water vapour from the gas to the condensate film. Much original work on this subject is done by the chemical engineers of the staff of the laboratory. The removal of impurities such as ammonia from gas involves washing processes in which the type of packing in the scrubber is important. Pilot-plant studies of grid and ring packings have led to improvements in the design of full-scale plant.

The gas industry in Britain is at a stage where far-reaching changes in its techniques are needed, and the Gas Council's research stations are fully occupied with the experimental work on which new production methods will be based.

# MYXOMATOSIS

The Mammal Society of the British Isles held a symposium on myxomatosis at the London Zoo on November 5; Dr. L. Harrison Matthews took the chair.

Mr. H. V. Thompson (Ministry of Agriculture, Fisheries and Food) gave a general historical introduction and then described the main aspects of myxomatosis in Britain, pointing his description with evidence derived from other countries affected by the disease. Careful records have been kept of outbreaks of myxomatosis in Britain and, since the first notification of the disease in October 1953, it has spread over most of England, Wales and Scotland, although pockets of rabbits still survive in many places. In Continental Europe, the disease has spread from France to Belgium, Luxembourg, the Netherlands and Germany and, more recently, to Austria, Italy, Spain and Switzerland.

Since the first epizootic of myxomatosis in Australia during 1950–51, there has each summer been a similar epizootic, depending for its effectiveness mainly upon the presence and activity of adequate numbers of mosquito vectors. The natural spread of myxomatosis in Australia has been rapid, and, even when moving slowly, speeds of three miles a day have been recorded. In Britain, however, natural spread has been much slower, averaging three and a half miles a month in one carefully checked area. This slow spread, in an area where woodland mosquitoes were abundant but did not bite either wild rabbits or caged domestic rabbits, indicated that mosquitoes were not important vectors in Britain, and the rabbit flea has, in fact, been found to be the principal vector.

Mrs. G. Lane (Hon. Miriam Rothschild) considered the main vectors in her paper, stating that far too little is known of the natural history of the rabbit flea (*Spilopsyllus cuniculi*) and stressing the need for more research. In Northamptonshire all wild rabbits were infested with this flea, and a dense rabbit population is usually heavily infested. It may be found that in areas sparsely populated with rabbits, fleas are correspondingly few; it is possible that as the rabbit population falls, due to myxomatosis, so will the numbers of fleas on the remaining rabbits, a natural check being thereby offered to the disease. If a rabbit becomes infected with myxomatosis, then the infection spreads rapidly to all the fleas on that rabbit. The fleas are found to concentrate on the head and ears of the rabbit. It is interesting to note that when an infected flea bites a rabbit on the ear, the incubation period of the disease is much longer than after a bite on the head.

The grey squirrel flea (*Orchopeas howardi*), which can also be made to feed on rabbits, can become infected and be a reservoir of the virus for up to twenty days; the same may be true of other fleas.

The rabbit flea in Australia is a different species from that in Britain, and is a poor vector. Much of the work on vectors in Britain had been done by Dr. Muirhead Thomson, who was unfortunately unable to be present. The only mosquito so far implicated in the spread of myxomatosis in Britain is *Anopheles maculipennis atroparvus*. It has been found carrying infection in the same hutches as myxomatous rabbits. Unlike other British mosquitoes, *A. m. atroparvus* may live throughout the winter, feeding at intervals; but Mr. P. G. Shute considered that, since this mosquito rarely bites in the open, it is not likely to be an important vector. Dr. C. H. Andrewes pointed out, however, that the virus survives in the mosquito for as long as six months and, unlike many viruses, the titre of which falls initially and then builds up, the myxoma virus maintains its level in *A. m. atroparvus* with very little change. It is thus difficult to determine whether or not there is a multiplication of the virus in this mosquito.

Mr. J. R. Hudson (Ministry of Agriculture, Fisheries and Food) stated that myxomatosis is not readily transmitted by mechanical contact, such as wiping the nasal secretions from an infected rabbit on to a clean one, or by infected herbage. He also stated that animals of many different species, suspected of infection with myxomatosis, have been examined in his department; but with the exception of two hares there was no evidence of the disease affecting other animals. Five hares have been found in France with clinical myxomatosis, the disease being transmissible to rabbits but not to other hares.

Immune rabbits have been bred; but so far none of the progeny has shown any evidence of immunity. The residual rabbits in most parts of Britain are susceptible to myxomatosis; but in one area, part of Sherwood Forest in Nottingham, many rabbits have survived the disease and developed immunity. The strain of the virus is here much reduced in virulence, producing nodular lesions which contain fully virulent virus during the early stages but attenuated virus during the later stages. Attenuated field strains of myxoma virus have been recovered from several parts of Australia during the past two years, and this year have also been found in France.

The diet of foxes was discussed by Mr. H. V. Thompson in the light of stomach analyses being done in his department. He emphasized that the work is not yet complete; but that comparison with the results obtained by Southern and Watson fifteen years ago showed that there has been an increase of field voles, brown rats and vegetable matter in the diet of the lowland foxes, after myxomatosis. Similar changes in diet were also noted by Mr. H. N. Southern at Oxford. The small-mammal population declined considerably in the summer of 1955 following the arrival of myxomatosis, and the runways of mice and other small mammals were dug up by foxes. There has, however, been some recovery in the small-mammal population during the past autumn. Southern also noted a very low reproductive-rate among the resident population of tawny owls on the Wytham Estate, Oxford, and there was some evidence that foxes, and also stoats, had produced smaller litters than usual this year.

Dr. N. W. Moore (Nature Conservancy) described very striking reductions in the breeding of buzzards, few birds having produced eggs in areas affected by myxomatosis; but in the areas to which the disease had not spread by spring of this year, the reproduction-rate was normal. There is also evidence that buzzards are moving about much more than previously, although spread in the range of buzzards has been taking place for some years.

Hares appear this year to be colonizing areas vacated by rabbits, and to be more frequently found in woods than hitherto; they also appear to be more abundant than in 1954, but it is too early to impute these changes to the effects of myxomatosis. The situation is also complicated by a number of introductions of hares into Cornwall, Pembrokeshire and elsewhere.

There is already good evidence of the recovery of the rabbit population in areas which were considered to be largely cleared by the disease. Southern stated that at Wytham Estate, near Oxford, only three rabbits' tracks were seen during the winter of 1954–55, whereas many thousands of rabbits were present before the onset of myxomatosis; now twenty burrows have been reopened. Similar reports came from several parts of Britain.

Dr. A. S. Thomas (Nature Conservancy) reported striking botanical changes following the great reduction of rabbits. He took photographic records of particular areas before the onset of myxomatosis, and compared these with more recent photographs. Detailed records of the changes have also been made since March 1954 along transects in ten places, mostly on declared or proposed Nature reserves on the chalk; the total length of these transects is more than 23,000 ft., and fifty point quadrats are recorded on every 100 ft. once or twice yearly. The early results of this method are very encouraging. The grasses are higher, there is much better ground cover and a greater range of species, especially of the more palatable grasses and clovers which were grazed by the rabbits. Woody plants, especially ling and gorse, which were closely grazed by rabbits, have made much growth; in the case of gorse the shoots have been up to 18 in. long in twelve months.

There has been not only marked vegetative growth, but also a wonderful show of flowers, both of the common ones like cowslip and rock rose and also of the less common orchids, which have appeared in profusion in places where they were not previously noticed, because rabbit grazing prevented flowering. One interesting result of the disappearance of rabbits has been the great profusion of ragwort in some places during the summer; the plants colonized rabbit-grazed turf, but rabbits also prevented many of them from flowering.

Many plants which have been relatively common in areas of intense rabbit infestation have owed their abundance to the fact that they are unpalatable or poisonous and could flourish when rabbits ate down and killed more palatable species. Such plants include viper's bugloss, hound's tongue, deadly nightshade, stinging nettle and elder, all of which flourished on the disturbed and manured soil around rabbit holes. It is too early to look for marked changes in these plants; but already elder bushes are suffering in some places from the absence of rabbits, because increased stocking with cattle to utilize the increased grass has resulted in the barking and killing of elder. Increased stocking should also control the growth of other woody plants which are appearing in grassland areas now that they are no longer being eaten back by rabbits.

Mention was made by Mr. H. N. Southern (Bureau of Animal Population, Oxford) of the great increase in tree cover on the Wytham Estate, Oxford; ash and particularly oak saplings are appearing where they were scarcely seen before.

Mr. W. Ives, scientific liaison officer in London of the Commonwealth Scientific and Industrial Research Organization, Australia, spoke of the remarkable changes which have occurred in the vegetation in Australia since the rabbit population was reduced, saying that grass is now growing well in places that had been virtually desert and that, in some areas, land capable of carrying one sheep previously now carries two cows.

Kenneth M. Backhouse
Harry V. Thompson

# BIOCHEMICAL AND MICROBIOLOGICAL RESEARCH IN HUNGARY: SOME IMPRESSIONS

A generous invitation to spend three weeks this summer as guest of the Hungarian Federation of Technical and Scientific Societies (METESZ) enabled one of a party of six British and four French scientists to see something at first hand of recent academic research in biochemistry and microbiology in post-war Hungary. Damage and losses suffered during the War, the economic and social revolution and the reorganization of academic research under the ægis of the greatly enlarged and reconstituted Academy of Sciences have resulted in big changes and considerable expansion in research programmes. At the same time, they have inevitably led to many administrative difficulties, and heavier teaching responsibilities (associated with an increase of more than four-fold in the number of university students).

Academic research is also still handicapped in many parts of the country by shortage of specialized equipment. The more complicated laboratory apparatus such as high-speed centrifuges, spectrophotometers, electron microscopes, etc., is not manufactured in Hungary and has to be imported from the U.S.S.R., Germany and Czechoslovakia. This means that such instruments are only rarely available. There have also been delays and difficulties in obtaining radioisotopes, which are now, however, beginning to arrive from the Soviet Union.

Hungarian biochemistry has suffered much from the departure of Prof. A. Szent-Gyorgyi, together with several of his most valued younger colleagues, to the United States in 1947. This gap, however, is gradually being filled by the younger generation of biochemists led by Academician F. B. Straub (a former pupil of Szent-Gyorgyi), director of the Institute of Medical Chemistry in the Medical University of Budapest, and by Prof. E. Szorenyi, head of the Biochemical Institute of the Academy. Straub's department of sixteen workers is devoted primarily to a study of protein synthesis. In spite of old and unsuitable accommodation (the city was terribly damaged during the siege early in 1945 and much rebuilding is still needed), this group has been doing important work and has recently succeeded in demonstrating the production of amylase by a mitochondrial preparation from homogenates of pig and pigeon pancreas and the formation of pepsinogen by homogenates of gastric mucous membrane. Other work includes the study of induced penicillinase synthesis by protoplasts of *Bacillus cereus* (Dr. M. Kramer) and the development of a technique of reversible 'hæmolysis' of red blood cells (Dr. S. Manyay) whereby they are rendered temporarily permeable to adenosine triphosphate and other substances, without actual disruption of the cell membrane.

A group of young and enthusiastic protein chemists at the Biochemical Institute has a wide programme which includes (*a*) the study of scleroproteins, in particular the relationship between procollagen and collagen in mammalian skins and fish swim bladder (Dr. I. Komyat); (*b*) a comparative immunochemical investigation of serum albumens from horse, donkey and mule (Dr. F. Antoni); (*c*) an enzymological comparison of crystalline triosephosphate dehydrogenases from yeast, mammals and crustacea (Dr. P. Elödi); and (*d*) the specificity and speed of action of proteinases (for example, trypsin) on homologous and heterologous proteins (Mrs. G. Szabolcsi).

One of the most distinguished figures in Hungarian microbiological research is Academician G. Iványovics, director of the Microbiological Institute in the Medical University of Szeged, who is well known to many British and American microbiologists. This University was moved from Kolozsvár when Transylvania was handed over to Roumania after the First World War. The buildings are relatively new, well designed and pleasantly situated in one main group in this attractive town of 100,000 inhabitants on the River Tisza. Prof. V. Bruckner, of Budapest, has recently succeeded in synthesizing a D-glutamic acid polypeptide, which Iványovics has found to be chemically and immunologically similar to the polypeptide he originally isolated from the capsule of *Bacillus anthracis*. Iványovics is also studying the properties of a high-molecular weight substance—'megacin'—isolated from *Bacillus megaterium* after ultra-violet irradiation, which appears to be a type of 'bacteriocin', specifically able to lyse cultures of *B. megaterium*. Other work in this Institute includes research on animal viruses, typing of influenza strains, etc., and some interesting studies by Dr. L. Alföldy on a bacteriophage of *Pseudomonas aeruginosa* having properties intermediate between those of a virulent and temperate phage.

Another medical university is in Debrecen—a quiet town of about the same size as Szeged 140 miles due east of Budapest, with important historical traditions (it was declared the capital of the short-lived independent Hungarian Republic during the war of liberation led by Lajos Kossuth against the Hapsburg dynasty a century ago). Its main university was founded in the fourteenth century only a few years after the University of Budapest; but most of the present buildings are comparatively new and the medical university was built during and after the First World War in a pleasantly wooded park on the outskirts of the town. It consists of well-designed separate buildings for each department and related hospital clinics, connected by a system of underground corridors. Here, in the Institute of Pharmacology under the leadership of Prof. T. Vályi-Nagy, a small group of microbiologists is studying antibiotics. An interesting new compound—'primycin'—produced by a species of actinomyces isolated from the intestine of the wax moth, has been crystallized and found to inhibit the growth *in vitro* of both *Mycobacterium tuberculosis* and *Staphylococcus aureus* at a concentration of 0·02 µgm./ml. It is unfortunately too toxic for general use, but some promising preliminary results are reported after local application in superficial infections. Among other work, the inhibitory action of streptomycin on growth of the organism which itself produces this antibiotic (*Streptomyces griseus*) is being studied by Dr. G. Szabó.

Back in Budapest, at the Institute of Microbiology of the Medical University, an opportunity was afforded of seeing a technically very well-produced film, shown by Drs. I. Juhász and J. Vadász, of the remarkable phenomenon of cell regeneration from an apparently acellular degenerated mass of granular protoplasm formed after treatment of a strain of *Salmonella enteritidis* with high concentrations of penicillin.

Finally, specific mention should be made of the Institute of Genetics in Budapest where, apart from other work on higher plant genetics, Prof. B. Györffy has recently established a microbiological section comprising five workers covering a wide range of subjects: (*a*) heterokaryosis in *Penicillium* (Dr. Igali); (*b*) streptomycin resistance in *Serratia marcescens*; (*c*) nucleic acid chemistry (Dr. Thomas); and (*d*) transformation, by deoxyribonucleic acid extracts, of *Rhizobium* species (Mrs. R. Balassa), using streptomycin-resistance and ability to form nodules on the alfalfa plant as genetic characters, which appear to be transmitted independently of each other. After early difficulties, not unconnected with the attitude to genetics prevailing five years ago, when Györffy's department was in danger of becoming a subsidiary section of the Agricultural University, his Institute is now being fully supported, as an independent research centre, by the Academy.

All this, of course, represents nothing more than a glimpse at some of the research work at present being done in Hungary. Although far better supported than before the War, academic research still suffers, perhaps, from the relatively greater emphasis laid on applied research—in industry and in the technical and agricultural universities. This is understandable—perhaps inevitable—in view of the determined efforts at industrialization of what was primarily an agricultural community. It shows itself, especially, in some shortages of specialized equipment and the great difficulties in obtaining technical assistants, who are attracted into industrial establishments by salaries up to twice those which they can earn in institutes of pure research (a problem not exclusive to Hungary).

Although excellent library facilities (which compare favourably in some cases with those provided in similar British research centres) have allowed Hungarian scientists to keep closely in touch with recent advances in the West, this cannot compensate for the rarity of direct personal contact. Unfortunately, during the past few years, opportunities for direct contact have been largely restricted to countries in Eastern Europe. One of the most lasting impressions obtained from this recent visit was the repeatedly expressed desire to re-establish closer contact with Western scientists. The more favourable political climate should make it easier to remove the obstacles still present (on both sides) to a freer exchange of visits, and might perhaps even abolish some of the restrictions to normal trade relations which at present prevent the import of badly needed British scientific research equipment into Hungary. A conversation with Academician Bognár, general secretary to the Hungarian Academy of Sciences, gave grounds for hope that the Academy might actively support projects for a more liberal exchange of visits of individual scientists between Britain and Hungary in the near future.

Meanwhile, it is encouraging to learn that a party of Hungarian scientists has recently visited Britain, under the auspices of the World Federation of Scientific Workers and the British Association of Scientific Workers; and that METESZ is to repeat its group invitations (begun in 1954) to British and French scientists next year. METESZ and its hard-working and imaginative secretary (Dr. E. Valko) and assistant secretary (Mrs. Barbara Striker) are indeed to be congratulated on having taken one of the first steps to break the ice. M. R. POLLOCK

# DEVELOPMENT AND WELFARE IN THE BRITISH COLONIES

THE schemes made under the Colonial Development and Welfare Acts, covering the period April 1, 1954–March 31, 1955, which are detailed in the latest return*, bring the total commitments for development and welfare schemes under the Acts to £123,402,271, and for research schemes to £12,908,139, of which £14,757,289 and £533,548, respectively, are for the year in question. Of this last sum, £133,157 is for agriculture, £83,767 for medicine, £54,413 for locust control, £47,589 for insecticides, £25,553 for social science, £9,042 for economic research, £6,795 for products research, £6,200 for fisheries and £2,250 for tsetse and trypanosomiasis.

Of the actual research schemes, £104,024 was for the establishment and maintenance for two years of the East African Scientific and Industrial Research Organization, a further £42,500 for the East African Medical Survey, £50,000 for the establishment and maintenance of the Colonial Road Research Section at the Road Research Laboratory, Harmondsworth, a further £37,750 for the maintenance of the Anti-Locust Research Centre and extra-mural activities, £31,483 for the purchase of buildings at Kavete for the East African Veterinary Research Organization, £22,329 to establish an Agricultural Research Station at Aden, £17,780 for sylvicultural research in Nyasaland, a further £16,365 to maintain the Ebini Livestock Experimental Station in British Guiana, a further £16,663 for the Desert Locust Survey and £14,390 for the maintenance of the Colonial Insecticides Research Unit at Porton.

In West Africa, £10,955 was provided for the establishment of a Standing Advisory Committee for Agricultural Research and a further £5,306 for the establishment of the West African Building Research Organization, as well as £4,500 for a social and anthropological investigation of the State of Gonja, Gold Coast. In East Africa, a further £8,100 was provided for control of coconut palm pests in Zanzibar; in the Western Pacific, a further £6,832 for investigation of means of controlling *Amblypelta cocophaga* and other coconut pests in the British Solomon Islands; in Sarawak, £4,300 for an investigation into the control of pepper disease; and in the West Indies, a further £4,230 for cytogenetical research on sugar cane and £6,780 for a pilot scheme for establishment of a Nutritional Research Unit in Jamaica.

Among the major development and welfare schemes of particular scientific interest are the following: in East Africa, a further £700,000 for the desert locust control campaign and £785,438 to intensify African agricultural development in Kenya during 1954–55; in Malaya, £408,250 for the construction of a road between Temerloh and Maran, linking the west and east coasts, £204,000 for the establishment of rural health centres, and £410,000 for the construction of a teachers' training college at Penang in British Guiana, and a further £72,750 for geological survey, as well as £35,000 for aerial survey and £20,833 for hydrographic and hydrological surveys. In British Honduras, a further £38,075 was provided for the artificial regeneration of pine, £29,555 for rice investigation and £45,200 for afforestation of pine savannah. Among a series of grants to the University College of the West Indies are £10,000 for the establishment of a Department of Chemical Technology and a further £10,000 for scientific equipment. £11,450 was provided for rice research in the British Solomon Islands Protectorate, and £33,500 for an aerial survey of Fiji. In West Africa, besides £99,314 for senior staff housing for the Nigerian College of Arts, Science and Technology, a further £150,000 for road development in the Cameroons and various contributions to Fourah Bay College (including £27,000 for additional laboratory and library accommodation), a supplementary contribution of £3,763,351 to the Development Plan for Nigeria includes substantial grants, distributed over all the regions, for agriculture (totalling £615,113), general education (£527,828), technical education (£455,478), forestry (£83,315), leprosy control (£217,793), medical and health (£884,909), veterinary (£125,244) and fisheries (£38,437).

# ECONOMIC DEVELOPMENT OF BASUTOLAND, BECHUANALAND AND SWAZILAND

A WHITE Paper on the High Commission Territories of Basutoland, Bechuanaland and Swaziland* gives a concise picture of the economic development and social services in these three territories, to which since 1945 nearly £14,144,000 has been granted or earmarked. Of this, nearly £3¾ million was from Colonial Development and Welfare Funds available for 1945–56, and a further £3 million has been allocated under the 1955 Act for the period to 1960. The Colonial Development Corporation has embarked on projects in the Bechuanaland Protectorate and in Swaziland, for which capital sanction of £7,299,000 has been given; of this amount, £4,424,000 had been spent by the end of 1954, and, according to present plans, full development of these projects may involve expenditure of another £10 million, not necessarily all from public funds.

---

* High Commission Territories: Economic Development and Social Services. Pp. 20. (Cmd. 9580.) (London: H.M.S.O., 1955.) 9d. net.

Reviewing the more important results of this investment, the White Paper emphasizes that, as a result of a campaign against soil erosion, the whole of Basutoland will be fully protected against erosion during the next few years ; and it is also hoped that, by reclaiming existing dongas or gullies by damming and planting trees, the water-table throughout the whole of the lowlands will be raised, with much benefit to pasturage and crop yields. The agricultural techniques best suited to Basutoland are being determined at an agricultural experimental station at Maseru and at twelve sub-stations, and a complete catchment area is being developed intensively to demonstrate how better land-utilization can increase productivity as well as prevent soil erosion. Other measures have considerably improved the quality and value of the Basutoland wool clip, and, besides some improvement of the lowland road system, a road to continue sixty-eight miles into the mountainous interior is under construction and is expected to be completed during the next two years.

In the Bechuanaland Protectorate much effort has been given to the improvement of water supplies in the settled areas in the eastern part of the reserves, while attention has also been given to the improvement of the quality of the cattle as well as the control of foot-and-mouth disease. The opening of an abattoir and cold-storage plant in Lobatsi in October last year will enable producers of first-grade animals to sell their beasts in peak condition and help to prevent disruption of marketing arrangements caused in the past by outbreaks of foot-and-mouth disease. On one of two large cattle ranches established in the Protectorate, the Colonial Development Corporation has made available watering facilities and large areas of grazing to a co-operative body of cattle exporters for rearing young animals in better conditions. Better farming methods are also being demonstrated, and a geological survey has confirmed deposits of minerals such as copper, coal, asbestos and kyanite.

In Swaziland, where the territory's revenues have been doubled during the past few years, significant improvements over the whole field of African activity —agriculture, cattle, water supplies, health, hygiene and education—have been obtained by a rural development scheme in which development teams are concentrated on chosen areas. Under a native land settlement scheme, conservation farming, grazing control and efficient crop production are practised in model settlements under government supervision. Some 160,000 acres have been planted with pine trees, and the possibilities of irrigated farming are being explored. About 30,000 acres are already irrigable, and it is intended to irrigate some 30,000 acres in north-east Swaziland. In these projects a variety of crops, including rice, bananas, citrus fruit and vegetables, are already being produced, while an important livestock and dairying industry has done much to reduce the incidence of stock disease.

Although the first essential is to develop the wealth and resources of all three territories so as to increase their revenues and make possible a general improvement in the standard of living of their inhabitants. expenditure on medical services has also greatly increased, and further greatly needed improvements are planned. In Basutoland, where there is now one doctor to every 21,600 persons and one hospital bed to every 1,250, more accommodation is to be provided during the next five years for patients suffering from tuberculosis, and a new mental hospital is to be built, which will be open to patients from all three territories. In Bechuanaland there is now one doctor to every 17,000 persons, and one hospital bed to every 555, and efforts are being made to provide adequate facilities in rural districts. In Swaziland the objectives, for which more than £200,000 has been granted during the past ten years from Colonial Development and Welfare Funds, have included the eradication of malaria (incidence of which has been reduced from 5,750 cases in 1948 to 765 in 1953) and the expansion of medical services in the low veld to meet a redistribution of population.

Special interest is attached at the moment to the development of African education. In Basutoland, where most schools are run by missions with financial assistance from the Government, a ten-year educational development plan was formulated in 1946 ; by the end of 1954 more than three hundred schools had been erected, altered or repaired, and the Lerotholi Technical School, with accommodation for boarders, had been built. A further five-year plan is proposed for building an agricultural training school and six new junior secondary schools and to separate secondary education from teacher-training at the Morija training school. In Bechuanaland, two junior secondary day schools and two secondary boarding schools have been built, the percentage of qualified teachers raised from 40 per cent to 52 per cent and the average size of classes reduced from 56 pupils to 33. Under a further programme a new teacher-training college, a trade school and four new junior secondary schools are to be built and the Bamangwato College enlarged and run as a secondary school for the whole Protectorate. In Swaziland, where enrolment in schools has increased by 80 per cent during the past ten years, further developments are also contemplated beyond those for which grants exceeding £175,000 have been made since 1945 from Colonial Development and Welfare Funds.

# PENTAGONAL SYMMETRY IN NATURE

In the various papers and books on the nature of organic symmetry, there is surprisingly little comment on pentagonal or pentamerous forms. This is not because of a rarity of occurrence of objects displaying such characteristics, for, although not ubiquitous, five-part units are common in both animal and plant design. One of the reasons for such a situation is that the pentagon does not lend itself to readily understood physical and mathematical notions of utility and function as do the hexagon and equilateral triangle. None the less, several groups, including both animals and plants, have developed either a five-part symmetry as a whole or special structures with a five-part symmetry, and their significance has recently been discussed by C. M. Breeder, jun. (*Bull. Amer. Mus. Nat. Hist.*, 106, Art. 3 ; 1955. Pp. 48 ; 1.50 dollars).

The number five and pentagonal designs have figured prominently in ancient mythology, magic and theology, and still exist in numerous present-day symbolic designs. Not the least interesting aspects of such considerations are found in some of the dynamic consequences of five-part symmetry. These consequences extend into the behaviour patterns both of those organisms possessing it in some form and of those reacting in some way to designs of this order. Organisms as different as honeybees and men clearly show striking attitudes and responses with respect to this form of symmetry.

Breeder's studies were based on prominent and varied echinoderm fauna as well as a striking number of five-petalled flowers, such as *Hibiscus*. His findings show that pentagonal order is common in some groups and is absent in others; there is little casual or incidental occurrence. It appears as the basic pattern of flowers, of dicotyledons, of echinoderms, of the vertebrate body section, of the distal ends of tetrapod limbs, and of the oral armature of priapulids. Its occurrence elsewhere is not common but includes the following cases: the tarsi of half the super-families of beetles have uniformly five segments, the other half showing various reductions in the number of segments; the ancestrula of certain bryozoans is pentagonal, although all subsequent individuals are hexagonal.

Five-partness, where it appears, is held to with great rigidity, even when extensive evolutionary change has taken place. This does not seem to be the case to such a marked extent with other symmetries, as the coelenterates show; here the group is marked by a considerable symmetrical instability.

# A PROJECTION INSTRUMENT TO AID IN THE DETERMINATION OF MESOMORPHIC AND POLYMORPHIC TRANSITION TEMPERATURES

By Dr. G. W. GRAY and A. IBBOTSON
Chemistry Department, University of Hull

THIS instrument consists of a simple optical system to be used in conjunction with the electrically heated microscope block[1] for the measurement of mesomorphic and polymorphic transition temperatures in the range room-temperature to about 380° C. Such transition temperatures are determined[1] on a mounted specimen, which is inserted in the slide slot of the heating block so that, by means of the optical system, its image is projected on to a screen. The detail which can be seen in the image is very much less than when the sample is observed using a microscope; but it has been found that transitions can be observed with equal accuracy and facility. The projection of the image on to the screen has the advantage that the eye strain involved in carrying out large numbers of determinations of transition points is completely eliminated. This is of significance in any investigation into the effects of changes in chemical constitution on the mesomorphic behaviour of organic compounds[2].

Fig. 1 illustrates the constructional and optical details of the projector. The light source (*A*) is a 500-watt projection bulb, which is mounted vertically in a well-ventilated lamp housing. The light beam passes horizontally through an aperture (2 in.) and is reflected vertically downward by the mirror *B*, through a condenser *C*, a sheet of heat-absorbent glass *D*, the mounted specimen (*E*) in the heating block, a projection lens *F*, on to a mirror *G*, and from there to the screen *H*. Two sheets of 'Polaroid' ($P_1$ and $P_2$), 2 in. in diameter, the uppermost capable of rotation about a vertical axis, enable the sample to be viewed in normal or polarized light. Using a 4-in. focal length projection lens, and a distance of 20 in. from the screen to the mirror *G*, the ¼-in. diameter specimen provides an image of diameter 3½ in.

The arrangement of this optical system relative to the instrument as a whole is also shown in Fig. 1. All parts are attached to two vertical steel tubes, 6 ft. long and 2 in. in diameter, carried on a stout wooden base, 18 in. square. The platform which carries the heating block is 8 in. square and is supported, at the two corners away from the main stand, by two pillars 23 in. long. A 6-in. square of ¼-in. thick asbestos is screwed to this platform, and through both is drilled a ¼-in. diameter hole. The heating block is arranged centrally over this hole. The 'Polaroid' ($P_2$), the projection lens, and the mirror *G* (4 in. × 3 in.) lie below this platform, and all three may be moved independently in a vertical plane. The superstructure above the platform, also

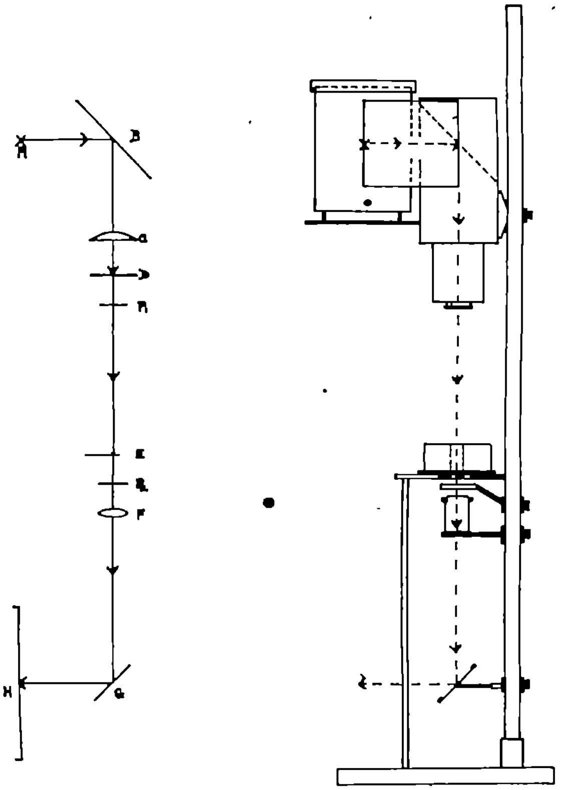

Fig. 1

movable in a vertical plane, consists essentially of two hollow brass cylinders. The first of these (10 in. long and 6 in. in diameter), containing the mirror *B*, is closed at the top and the 4-in. diameter hole at the bottom carries the condenser. A subsidiary cylinder, 4 in. in diameter and 4 in. long, screws in below this cylinder. Mounted in this cylinder is the heat-absorbent glass, and the lower end is closed by the rotatable 'Polaroid' $P_1$. This 'Polaroid' is mounted in a brass ring with a serrated edge which facilitates its adjustment, and carries a 0–360° scale. The other major cylinder (11 in. long and 8 in. in diameter) constitutes the lamp housing and is attached to the first cylinder by two brass sheets riveted to both cylinders. The gaps above and below are covered by brass sheet to eliminate the scattering of light. The base of the lamp housing is a 9-in. diameter disk which carries the lamp, but is held at least one inch clear of the cylinder base. The top of the cylinder is covered by a 9-in. diameter lid which is supported by brass strips about an inch above the cylinder top. These precautions were taken in order to ensure adequate ventilation of the lamp housing. The light beam passes through 2-in. diameter holes in the cylinders and thence to mirror *B*.

As a result of standardization against measurements made on the heating block in conjunction with a microscope, the following procedure was adopted for determination of melting points, mesomorphic and polymorphic transition temperatures. The nematic- or smectic-isotropic transition is taken as the temperature at which the last trace of anisotropic mesophase disappears from the image in polarized light. In the same way, the smectic–nematic transition temperature is that at which smectic characteristics can no longer be seen. In all cases, the above mesomorphic transition temperatures are reproduced when the sample is cooled. Similarly, melting points are given by the temperature at which all crystalline material vanishes from the image, and polymorphic transitions by the disappearance of one solid modification in another. [Aug. 30

# ACCELERATION OF ABSCISSION BY A FACTOR PRODUCED IN SENESCENT LEAVES

By DAPHNE J. OSBORNE

Agricultural Research Council Unit of Experimental Agronomy, Department of Agriculture, University of Oxford

NEARLY twenty years ago, La Rue[1] demonstrated that removal of the leaf lamina causes a rapid abscission of the petiolar stump; but if a small part of the blade is left attached to the petiole, abscission is retarded. He further showed that if indole-acetic acid mixed with lanolin is applied to the cut end of the petiole following removal of the lamina, then the effect due to the blade tissue is simulated since abscission is delayed. Other workers[2–4] have confirmed and extended these results, and many active plant growth-regulating substances are now known which can, like indole-acetic acid, retard abscission.

More recently, Addicott and his co-workers[5] have shown that if indole-acetic acid and certain other growth substances are applied to the petiole in a position proximal to the abscission zone, abscission may be accelerated. By means of tissue extraction followed by bio-assay[6], they have assessed the auxin content of the leaves and petioles of bean plants in different stages of development, and have shown that there is a gradient of natural auxin from leaf to stem, which falls as the leaf matures. On the basis of their accumulated evidence, these workers have suggested that abscission may be controlled by an auxin gradient across the abscission zone from leaf to stem. As long as this gradient is positive, abscission will not occur; but when the gradient falls to zero, either as a consequence of leaf senescence or removal of the leaf blade, separation will take place. When the gradient becomes reversed, following an increase in the proximal supply of auxin, abscission is accelerated.

Jacobs[7], in his comprehensive investigations with *Coleus*, has demonstrated that leaves, particularly those in the apical bud which produce the maximal amount of auxin, promote the abscission of nearby petioles from which the laminae have been removed. He also showed that abscission of the petiolar stumps is accelerated if the apical bud is removed and replaced by lanolin containing indole-acetic acid, and concludes that the auxin produced in the apex is, in part, transported down the stem and acts as a source of proximal auxin.

Ethylene gas has long been known to accelerate the abscission of intact leaves; the production of ethylene by plant tissues is well established, and Gawadi and Avery[8] have proposed that a balance between auxin production and ethylene production may control abscission in the leaf. Although ethylene and indole-acetic acid may have opposite and antagonistic effects on abscission[9], proof of the existence of such a balance has not, so far, been obtained.

During the course of experiments on leaf abscission, carried out over the past three years at Oxford, it has become apparent that there is a further controlling factor, namely, that as leaves mature and reach senescence they produce a chemical substance or substances which have the property of accelerating the abscission of intact abscission zones.

This chemical factor was first extracted into agar from the distal pulvini of senescent primary leaves of *Phaseolus vulgaris* using the classical methods of diffusion employed by Boysen-Jensen and Went. The bio-assay is a modification of a method originally described by Addicott[10], and the following is a brief description of the procedure.

The distal pulvini are excised from the primary leaves of *Phaseolus vulgaris* var. Canadian Wonder, and are placed, proximal side down, on 0·03-ml. blocks of 2 per cent agar. Each pulvinus is left in contact with its agar block for twenty-four hours at 24° C. under conditions of high humidity. Each agar

Table 1. Average time in hours for abscission of bean explants when (*a*) agar blocks containing diffusates from young or abscinded pulvini are applied to the pulvinar end; or (*b*) whole pulvini are sealed with agar to the pulvinar end

| Time for abscission (hr.) | | | | | |
|---|---|---|---|---|---|
| (*a*) | | | (*b*) | | |
| Control | Diffusate from young pulvini | Diffusate from abscinded pulvini | Control | Pulvini from attached leaves | Pulvini from abscinded leaves |
| Expt. 1<br>107 | 105 | 88 | Expt. 3<br>>120 | 55 (from senescent leaves) | 45 |
| Expt. 2<br>61 | 55 | 53 | Expt. 4<br>57 | 56 (from young leaves) | 37 |

block is then applied to the cut surface of a 1-cm. section cut from the petiole of a primary leaf of a bean plant. The sections, or 'explants', include the distal pulvinus, the abscission zone and part of the petiole. They are aligned on 'Perspex' racks mounted over 3 per cent agar in Petri dishes maintained at 24° C. Every few hours, the pulvinar end of the explant is given a light tap to determine if separation of the abscission zone has taken place. Twenty explants are used per treatment.

As the primary leaves grow older, it is found that explants cut from their petioles take progressively longer to separate. With those from very young expanding leaves, abscission is complete after 25–35 hours; but when plants are growing vigorously in midsummer, explants from fully expanded primary leaves may fail to separate by the end of six days. Explants from leaves of all ages have been used in the present studies, and the results quoted have been selected to include a wide range of test material.

It will be seen from Table 1 (*a*) that when a block of agar containing the diffusate from the pulvinus of an abscinded bean leaf is applied to the pulvinar end of an explant, the average time required for abscission is shorter than for the control. Blocks containing the diffusate from the pulvini of young expanding leaves produce no significant effect. From these and other experiments, it can be concluded that as the leaves become senescent and approach abscission the diffusate is progressively more effective in accelerating abscission. Confirmation of the increase in the power to induce abscission with age of leaf is obtained from further experiments in which sections of the pulvini are excised from leaves of different ages and sealed to the pulvinar end of explants by a 1-mm. disk of 2 per cent agar. The substance or substances present in the pulvini of senescent and abscinded leaves is found to diffuse across the agar seal and to accelerate abscission of the explant, see Table 1 (*b*). No comparable stimulation has been observed with pulvini from very young leaves.

When whole pulvini, or agar blocks containing the diffusate derived from them, are sealed to the petiolar or proximal end of the explants, instead of to the pulvinar end, acceleration of abscission is again obtained, indicating that, unlike indole-acetic acid, the diffusate is effective from whichever side it reaches the abscission zone.

Other experiments have shown that the production of this abscission factor is not confined to the lamina. Diffusates from the pulvini of abscinded explants cut from young leaves, and from petiolar stumps which are becoming senescent as a result of removal of the lamina, are both effective in accelerating abscission.

Experiments with many evergreen an deciduous species have demonstrated tha during the period of autumnal leaf-fall substances inducing abscission are of widesprea occurrence in the petioles of senescen leaves. Comparisons have been made of th diffusate from the petioles of yellow leave which have just completed abscission an that from green leaves which are stil attached to the branches. To do this a section from the leaf base 0·5 cm. long is placed proximal side down upon an agar block in the manner already described, and after twenty-four hours at 24° C. the leaf-base is removed and the block applied to the pulvinar or petiolar end of a bean explant. The results obtained for a selected number of trees and shrubs are listed in Table 2, and it is clear that an acceleration of abscission has resulted from the application of the diffusate from abscinded leaves of each species. The diffusate from the green leaves of the deciduous species, which at this time of year are fast approaching senescence, also accelerates abscission; but generally to a lesser extent. In the evergreen species, privet and *Rhododendron*, leaves in their first year of growth do not normally undergo abscission, and it is noteworthy that the diffusate obtained from the petioles of such green leaves is not found to accelerate abscission. It is only the diffusate from senescent leaves in their second or third year of growth which appears to be active. Diffusates from the first-year leaves of several *Rhododendron* species are, in fact, found to delay rather than hasten abscission.

A preliminary study of the diffusible factor from senescent leaves has revealed that it has the property of counteracting the retardation in abscission which results from treatment with indole-acetic acid. This conclusion is based on the following type of result. A 0·002-ml. drop of distilled water or an aqueous solution of indole-acetic acid (sodium salt) at 20, 50 or 100 p.p.m. is applied to the freshly cut surface of the pulvinar end of an explant. When the drop is completely absorbed, a block of plain agar or agar containing the diffusate is sealed to the pulvinar end. The results of such an experiment using the diffusate from *Pyrus aria* are given in Table 3 (*a*), and it is seen that although indole-acetic acid alone delays abscission the effect is partly or wholly reversed by the addition of the diffusate.

In other experiments, a block of agar or a segment of pulvinus from an abscinded primary leaf is sealed

Table 2. Average time in hours for abscission of bean explants treated at the pulvinar end with agar blocks containing diffusates from the petioles of previously attached or abscinded leaves

| Species | | Control | Diffusate from attached green leaves | Diffusate from abscinded leaves |
|---|---|---|---|---|

| 100 | 0 | 0 | 0 | 40 |

to the pulvinar end of an explant previously treated with a drop of indole-acetic acid. Typical results are given in Table 3 (*b*), and again this demonstrates that the diffusate from senescent pulvini counteracts the effect of indole-acetic acid.

The possibility that the factor could be ethylene has not been overlooked; but since explants in the process of abscission do not accelerate the abscission of intact explants enclosed with them, it seems unlikely that the active substance or substances can be gaseous.

On the basis of the present results it is proposed that leaf abscission may be controlled not only by endogenous auxins but also by some substance or substances which are produced as the leaf matures, and which reach a maximum at senescence. The question whether this factor is itself active in inducing abscission or whether it functions indirectly by altering the level of the effective auxins in the abscission zone must await the results of further investigations.

I am indebted to Miss Patricia Humphrys for carrying out the experiments with privet and to Prof. G. E. Blackman for his encouragement and for suggesting and supplying the two types of leaves from several species of *Rhododendron*.

# AN ASSOCIATION BETWEEN THE *P* AND *Jay* SYSTEMS OF BLOOD GROUPS

By Dr. RUTH SANGER

**Medical Research Council Blood Group Research Unit, Lister Institute, London, S.W.1**

THE system of blood groups called *P* was discovered by Landsteiner and Levine[1] in 1927. One antibody, anti-*P*, and one red cell antigen, *P*, define the system. The antigen *P* is inherited as a dominant Mendelian character; no antibody, and therefore no antigen, corresponding to the hypothetical allelomorphic gene *p* has yet been found. The phenotype $P-$, assumed to represent the genotype *pp*, has a frequency of 21·15 per cent in Europeans[2]. Traces of anti-*P*, active only at temperatures around 4° C., can be found in the serum of most $P-$ persons[2]. However, human sera containing anti-*P* strong enough for diagnostic purposes are a rarity. Marked variation in the strength of the *P* antigen in different samples of blood was noted by the discoverers[1]: the variation has been proved to be due, at least in part, to the homozygous or heterozygous state of the donor[3].

The *Jay* system of blood groups was discovered by Levine, Bobbitt, Waller and Kuhmichel[4] in 1951. One antibody, anti-$Tj^a$, and one antigen, $Tj^a$, define the system. The antigen $Tj^a$ is inherited as a dominant Mendelian character; no antibody, and therefore no antigen, corresponding to the hypothetical allelomorphic gene $Tj^b$ has yet been found. The phenotype $Tj(a-)$, assumed to represent the genotype $Tj^bTj^b$, is a great rarity: fourteen $Tj(a-)$ persons, members of eight families, have been found[4-11]. The agglutinin anti-$Tj^a$ is present in the serum of each of these people; most of the examples are also capable of hæmolysing $Tj(a+)$ red cells in the presence of complement. The frequency of the phenotype $Tj(a-)$ is not known: the propositi were brought to notice because of the antibody in their serum, but no random $Tj(a-)$ has been found though more than ten thousand white people have been tested[4-7,11].

Samples of blood from three unrelated $Tj(a-)$ people, Herr K.[11], Mrs. El.[8] and Miss Pa.[7], have recently been tested in this Unit and all three were $P-$. This was startling, for only one white person in five is $P-$. Reference to published work then showed that the *P* groups of three other unrelated $Tj(a-)$ persons and of one sib had been recorded, and all four were $P-$. The probability that six consecutive unrelated $Tj(a-)$ persons should be $P-$ merely by chance is too remote to be entertained. The blood groups of all the known $Tj(a-)$ people are given in Table 1.

The antibody, anti-$Tj^a$, was then investigated, with the attention thus directed to the *P* system. Six anti-$Tj^a$ sera were available (from Mrs. J.[4], Mrs. Mo.[5], Miss Pa.[7], Mrs. El.[8], Herr K.[11] and from a Swedish patient (Broman, B., personal communication)). Each serum after absorption with an equal volume of $P-$ red cells gave the reactions of anti-*P*. Most of the resulting anti-*P* sera were much stronger, and reacted at higher temperatures, than the 'naturally occurring' anti-*P* found in the serum of normal $P-$ donors.

Of one serum (Mrs. El.) there was plenty for more elaborate absorptions and elutions. All antibody

Table 1. THE BLOOD GROUPS OF $Tj(a-)$ PERSONS

|  |  | Her sister | $A$ | $MsMs$ |  | $CDe/CDe$ |  | − |  | − |  | + |  | − |  |
|  |  | Her brother (Yoi) | $O$ | $MsNs$ |  | $CDe/CDe$ |  | − |  | − |  | + |  | − |  |
|  |  | Her brother (Yas) | $O$ | $MM$ |  | $CDe/CDe$ |  | − |  | − |  | + |  | − |  |
| Germany | 11 | Herr K.* | $A_1$ | $MSNs$ | − | $cde/cde$ | − | − | + | − | − | + | − | − | + |

* The blood of the three people marked with asterisks was tested in this Unit. Miss Pa. is now in England; her $P$ and *Kidd* groups have not previously been published. Mrs. Hl. is now in England; her groups have not previously been published.

Miss Pa. secretes $H$ and $Le^a$ but not $A$ or $B$; Mrs. Hl. secretes $H$ and $Le^a$ but not $A$ or $B$; Herr K. secretes $A$ and $H$ but not $B$ or $Le^a$

could be removed by absorption with $P+$ red cells, and the ease of the removal was proportional to the strength of the $P$ antigen of the absorbing cells. Eluates from the absorbing cells, whether $P+$ or $P-$, reacted more strongly with $P+$ than with $P-$ cells.

But the best evidence of the direct relationship of anti-$Tj^a$ to the $P$ system was provided when the serum of Mrs. Hl. was found, after titration, to give lytic and agglutination reactions which were strongest with strong $P+$ red cells, a little less strong with weak $P+$ cells and a little less strong still with $P-$ cells.

A close relationship between the $P$ and *Jay* systems is therefore established. Though the nature of the relationship is not yet known, it is simplest to suppose that *Jay* is part of the $P$ system. The facts would fit surprisingly well if the $P$ system were constructed on the $A_1A_2O$ pattern. To fit this pattern, the gene $P$ has to become $P_1$, the gene $p$ has to become $P_2$ and the gene $Tj^b$ has to become $p$. Anti-$P$ becomes anti-$P_1$ (like $\alpha_1$ in the serum of an $A_2$ person) and anti-$Tj^a$ becomes anti-$P$ + anti-$P_1$ (like $\alpha + \alpha_1$ in the serum of a group $O$ person). Absorption and elution tests using anti-$Tj^a$ and $P+$ and $P-$ red cells give results directly comparable with the same tests using $\alpha + \alpha_1$ and $A_1$ and $A_2$ cells. There are doubtless other possibilities: $Tj^b$ might, for example, represent suppression of $P$ or $p$, but the $A_1A_2O$ model offers an easy way of understanding the relationship of the *Jay* blood groups to the $P$ system.

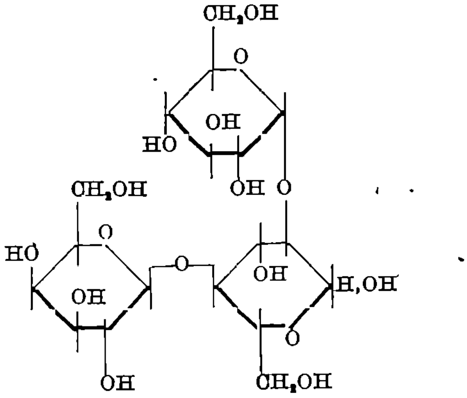
# ENZYMIC SYNTHESIS OF A 'BRANCHED' TRISACCHARIDE

By DR. R. W. BAILEY, DR. S. A. BARKER, DR. E. J. BOURNE and PROF. M. STACEY, F.R.S.

Chemistry Department, The University, Birmingham 15

EVIDENCE is now accumulating that oligosaccharides, rather than higher polymeric materials, are formed when dextransucrase acts on sucrose in the presence of relatively large amounts of certain simple sugars, which serve as chain-initiators (cf. refs. 1–3). In large-scale preparations of such oligosaccharides, it is often more convenient not to use a purified enzyme but instead to grow a dextransucrase-producing organism on a culture medium containing a high concentration of the chain-initiator in addition to the sucrose substrate[2]. For example, it was shown recently[3] that oligosaccharides (probably in the tri- and tetra-saccharide range) are produced when cultures of *Betacoccus arabinosaceous* (Birmingham strain) are grown on a medium containing yeast extract, inorganic salts, sucrose (2 per cent) and lactose (10 per cent). We now report the isolation, using the charcoal column technique[4], of a trisaccharide from such a culture, and describe the elucidation of its structure. This trisaccharide was chosen for investigation because it seemed from other studies (unpublished results obtained by us) that the αβ-D-glucose unit of the lactose was more likely to be the acceptor of the enzymically transferred glucose residue than was the β-D-galactose unit, in spite of the fact that the former constituted the reducing moiety. Such a transfer resulting in a novel trisaccharide synthesis was indeed found to occur, for the trisaccharide was shown to be O-β-D-galactopyranosyl-(1→4)-O-[α-D-glucopyranosyl-(1→2)]-D-glucopyranose (I).

Hydrolysis of the trisaccharide with $1 \cdot 5\,N$ sulphuric acid at 100° for 4 hr. gave a 96 per cent conversion (determined by cuprimetric titration) into glucose



(I)

and galactose ; visual comparisons on paper chromatograms indicated that the glucose/galactose ratio was approximately 2/1. Partial hydrolysis with 1·1 $N$ sulphuric acid at 90° for 1 hr. gave products with the $R_F$ values of galactose, glucose and lactose, together with a component ($X$) which was very similar to sophorose (2-O-β-D-glucopyranosyl-D-glucose) in its $R_F$ value and in the characteristic yellow-brown stain which it gave with an aniline hydrogen phthalate spray. Since it is the position, rather than the configuration, of the glycosidic linkage which governs the mobility of a disaccharide[5], this component could equally well have been 2-O-α-D-glucopyranosyl-D-glucose. While the reducing power of the trisaccharide towards alkaline hypoiodite[6] was 104 per cent of the theoretical value, that towards the Shaffer–Hartmann copper reagent[7] was only 0·3 per cent of the reducing power of glucose ; such a discrepancy between the results of the two methods is shown by 2-O-substituted glucoses (for example, the corresponding values for 2 : 3-di-O-methyl-D-glucose were 100 and 14 per cent, respectively) (cf. refs. 6 and 8).

Confirmatory evidence that the trisaccharide had the structure shown was obtained by four routes : (*a*) treatment with a phenylhydrazine acetate solution at 100° for 2 hr. gave glucosazone (melting point and mixed melting point 199–201°) and lactosazone (melting point and mixed melting point 193–195°), each of which had the same mobility as an authentic specimen when submitted to ionophoresis in aqueous formic acid (Whelan, W. J. (private communication), has used a similar method) ; (*b*) reduction of the trisaccharide with sodium borohydride gave the corresponding alcohol, which on partial hydrolysis yielded glucose, galactose and two disaccharide alcohols ($R_{glucose}$ 0·32 and 0·35), and which consumed 5·05 mol. of periodate in 24 hr. with the liberation of 0·85 mol. of formaldehyde and 1·8 mol. of formic acid (theoretical values : 5·0, 1·0 and 2·0, respectively) ; (*c*) the trisaccharide itself consumed 3·9 mol. of periodate and produced 1·85 mol. of formic acid (theoretical values, 4·0 and 2·0, respectively), leaving a residue which gave glucose on hydrolysis ; and (*d*) methylation of the trisaccharide (once with methyl sulphate – sodium hydroxide and thrice with methyl iodide – silver oxide), followed by acidic hydrolysis and paper chromatographic analysis of the products, revealed three main components, with the mobilities of 2 : 3 : 4 : 6-tetra-O-methyl-glucose, 2 : 3 : 4 : 6-tetra-O-methyl-galactose and 3 : 6-di-O-methyl-glucose, and traces of two slower-moving components, but no 2 : 3 : 6-tri-O-methyl-glucose.

The α-configuration of the new glucosidic linkage in the trisaccharide was indicated (*a*) by the high value of its $[\alpha]_D$ (+103° equil., *c*, 1·03 in water), and also that of its alcohol (+66·1°, *c*, 0·97 in water), relative to lactose (+52·6°, equil. in water) ; (*b*) by its infra-red absorption spectrum (930–750 cm.$^{-1}$), which displayed a peak at 843 cm.$^{-1}$ in addition to the peaks shown by lactose (cf. ref. 9) ; and (*c*) by the fact that with almond β-glycosidase it yielded disaccharide $X$, galactose and a trace only of glucose.

The enzymic synthesis of the trisaccharide has also been accomplished using a cell-free culture filtrate from the organism. Its identity with that described above was established by paper chromatography of the two samples, and of the products of partial and complete acidic hydrolysis, by comparison of their infra-red spectra and by determinations of reducing power and optical rotation. It is not possible at present, however, to decide whether the synthesis was effected by dextransucrase itself or by an accompanying enzyme.

Several important points of interest arise from this work, which has revealed a method for the enzymic synthesis of the rare α-1 : 2-glucosidic linkage. (Recently, Peat, Whelan and Hinson[10] detected the α-1 : 2-linked glucose disaccharide in a mixture of ten disaccharides formed from a glucose solution by an extract of *Aspergillus niger NRRL* 330.) We believe this to be the first enzymic synthesis *in vitro* of a 'branched' trisaccharide. The mechanism of its formation could be a general one for branched oligosaccharides ; it involves the use of a carbohydrate primer in which a sugar residue, other than the usual non-reducing end unit, has the correct structure for it to serve as an acceptor of a transferred sugar residue. Moreover, there is an indication of a possible route to the synthesis of branched polysaccharides which does not involve branching of a linear polymer as is the case with glycogen and amylopectin (cf. ref. 11) ; thus, a 'branched' trisaccharide in the form of a glycoside (for example, phosphate, fructosyl derivative) could well serve as a substrate for a transglycosylase which transfers the three sugar units *en bloc* to a growing chain of a branched polysaccharide. This work also raises the possibility that the non-terminal glucose units in an α-1 : 6-linked glucose polymer might serve as primers for the enzyme system studied above, giving rise to dextrans with a few α-1 : 2-branch points in addition to the α-1 : 3- and α-1 : 4-branches commonly found.

One of us (R. W. B.) thanks the Colonial Products Research Council for the award of a scholarship. The expenses were met by a grant from the Nuffield Foundation.

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Interference Photography of the Chromospheric Spectrum

The high resolution and dispersion available with interference spectroscopes such as the Fabry–Pérot interferometer has led to the development of standard techniques for their employment in the study of the Fraunhofer absorption spectrum[1]. Until very recently, no such success had attended efforts to observe interferometrically the emission spectrum of the solar corona and the chromospheric flash spectrum. Although the flash spectrum is much stronger than that of the corona, its interferometric observation is complicated by the fact that it is confined to an extremely narrow layer, which extends only some 10″ beyond the much brighter solar limb.

During the total solar eclipse of June 30, 1954, Jarrett and von Klüber succeeded[2] in obtaining measurable fringes in the green coronal line at 5303 A. An attempt by Brück and Jackson to photograph the chromospheric spectrum interferometrically during the total solar eclipse of February 25, 1952, failed to produce fringes, but the authors were able to conclude from their observations that the unblended lines included in their investigation[3] must have widths in excess of $1\cdot2$ cm.$^{-1}$, or $0\cdot24$ A. at 4471 A.

The stronger lines of the chromospheric spectrum can be observed in the uneclipsed sun by setting the slit of the spectroscope across or tangentially to the solar limb, so that it intersects the chromosphere. When observed by this method the chromospheric emission lines have superimposed upon them a Fraunhofer absorption spectrum produced by atmospheric and instrumental scatter from the sun's limb. Satisfactory observations of this kind can therefore only be made when a combination of suitable atmospheric conditions occurs.

During the summer of this year, the problem of photographing the interferometrically observed spectrum of the chromosphere of the uneclipsed sun has been investigated at the University Observatory, Oxford, and a series of satisfactory plates obtained. These show conspicuous fringe systems of the emission lines $H_\alpha$ (6563 A.), $D_3$ (5876 A.), $H_\beta$ (4861 A.), and of the $H$ and $K$ lines (3968, 3934 A.).

The instrument used for this work has been the new Oxford 35-metre solar tower, in which a 20-in. diameter paraboloid of fused quartz provides a solar image about 32 cm. in diameter. The image was formed on a screen containing a slot which selected a small region of the solar limb. The region so selected was re-imaged on the slit of a Hilger medium glass spectrograph, by means of a system comprising a field lens, collimator and camera each of 60 cm. focal length. The spectroscopic dispersion was about 40 A./mm. at 5876 A. The slit width was $0\cdot02$ mm. The solar limb was adjusted to be tangential to the slit, the point of contact coinciding with the base of the slit. Under these conditions, the full height of the slit, about 2 cm., corresponds to a height of 8″ (5,800 km.) above the solar limb. A Fabry–Pérot interferometer with a 1-mm. invar spacer was placed in the parallel beam between the auxiliary collimator and camera, and tilted so that several diametral sections from one side of the ring pattern would fall within the chromospheric region. The measured mean values of the reflectivity and transmission of the newly deposited silver coatings were $95\cdot5$ and $2\cdot5$ per cent at 5500 A., giving a theoretical resolving power of 260,000. Exposure times varied from 1 to 2 min., and during the exposure the solar limb was guided by means of an optical control.

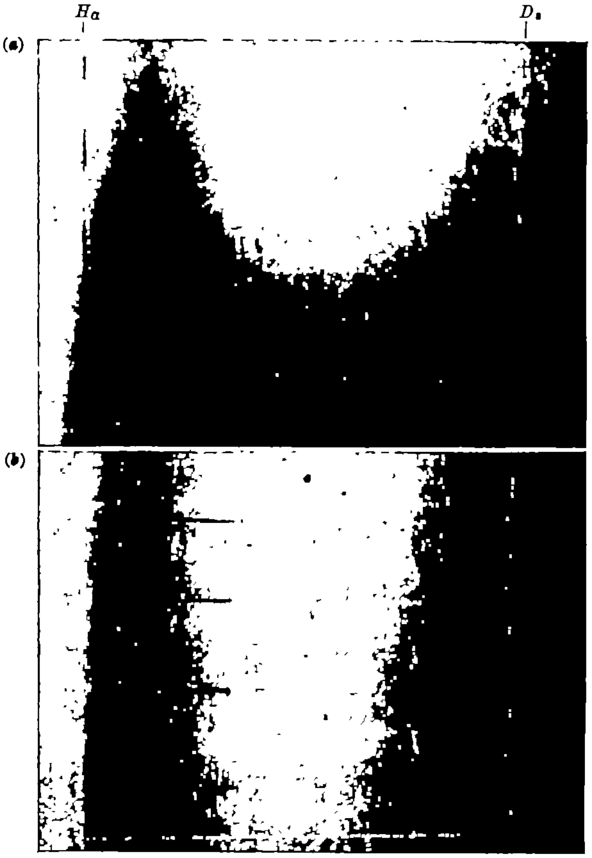

Fig. 1. Interference spectra of the Sun (negative prints) λλ 5700–6600 A. (a) Chromospheric $H_\alpha$ and $D_3$, and limb scatter spectrum from 500 to 5,500 km. above the solar limb. (b) Photospheric spectrum at solar centre with superimposed fringes of cadmium 6438 A

In addition to a pair of chromospheric spectra, the plates have a photometric calibration exposure and an interference spectrum of the solar centre, on which is superimposed a control set of fringes obtained by replacing the solar image by a cadmium discharge lamp and widening the slit. These features can be seen in Fig. 1, which is an enlargement of part of a typical plate. The Fraunhofer scatter spectrum in (a) and the centre spectrum (b) both show the well-known knotted appearance in the absorption lines. On the original plates, the very fine parabolic channels can be traced nearly to $H_\alpha$, where they become submerged in plate grain. In (a), fringes of the chromospheric helium line 5876 A. are seen in emission. The range between successive orders at this wave-length is $1\cdot73$ A., and from this the great width of the line is apparent. The control fringes of cadmium in (b) indicate that the actual resolving power is adequate to provide reliable profiles of this line. The fringe system of $H_\alpha$, which appears prominently on all plates, is more complicated and variable. In general, it appears to be wider than the range of the étalon

·1 A. at 6563 A.) in the lower chromosphere, but igher up it gives fringes which show self-reversal. the corresponding centre spectrum (*b*) the absorpon line of $H_a$ is also too broad to show fringes, and is absent.

A fuller account of this work and of the profiles the $D_3$ line in the latitude range covered will be ommunicated elsewhere.

# Palæomagnetic Study of Rocks from the Grand Canyon of the Colorado River

DR. S. K. RUNCORN has recently described easurements of remanent magnetization made on diments collected from the Colorado Plateau of rizona[1] and has compared these results with those ade on rocks of similar age from Great Britain. uring the summer of 1954 I also collected from e Grand Canyon of the Colorado River for the urpose of making studies of remanent magnetism n these rocks. I wish here to compare my results ith those obtained by Dr. Runcorn.

Of the many rocks exposed in the Grand Canyon, nly those of the Supai Formation (Permian Age) nd the Hakatai Shale (Algonkian Age) could be nown to have retained, up to the present, the agnetization they obtained on deposition. A comarison of the results obtained by Dr. Runcorn and yself is given in Table 1.

Table 1

| Authority | Formation | Magnetic declination | Magnetic inclination | Rad. of 95% probability | Deduced pole position |
|---|---|---|---|---|---|
| Runcorn | Supai | S. 47·8° E. | + 22·0° | 7·5° | 121° E., 26° N. |
| Doell | Supai | S. 34° E. | + 8° | 7° | 115° E., 30° N. |
| Runcorn | Hakatai* | S. 87·7° W. | + 72·8° | 5·4° | 150° W., 31° N. |
| Doell | Hakatai* | S. 66° W. | + 72° | 17·5° | 144° W., 18° N. |

* The magnetic directions are not corrected for geological dip (about 10°).

The angular difference between the average irections is 19° for the Supai rocks and 7° for the akatai rocks. It is very probable that Runcorn's irection for the Supai should be farther to the south ith a smaller inclination[3], thus bringing the angular ifference between the two sets of measurements ithin the probable error.

It is important to note that these measurements ere made entirely independently. Runcorn restricted is collection to the Kaibab Trail, whereas my ollections were taken equally from the Kaibab and right Angel Trails (separated by about 2½ miles). urther, Dr. Runcorn's measurements were made on n astatic type instrument, whereas mine were made n a 'rock generator' type magnetometer made available by the Stanolind Oil and Gas Co., Tulsa, Oklaoma. The comparison is very encouraging, in that e number of samples measured in each determination is of the order of ten to twenty.

No 'reversals' were found by Dr. Runcorn or me either the Supai rocks or the Hakatai rocks. Thus, if the main geomagnetic field reverses itself, as postulated by Hospers for the Tertiary[4], and by Clegg *et al.* for the Triassic[5], such reversals are not evident in the periods represented by the Supai and Hakatai rocks.

Details of this work will appear elsewhere after further studies of magnetic stability have been made.

I am indebted to the Institute of Geophysics, University of California, for a grant to cover expenses. This work forms a portion of a dissertation submitted to the University of California in partial satisfaction of the requirements of the degree of Ph.D.

# Anisotropy of Effective Gas Diffusion Coefficients in Extruded Carbon Rods

IT is well known that, in extruded cylindrical samples composed of either particles of amorphous carbon or graphitized carbon, the properties of thermal expansion, thermal conductivity and electrical conductivity are highly anisotropic[1]. The anisotropy in these properties is caused by the orientation of the irregular particles with their long side parallel to the direction of extrusion and by the inherent anisotropic behaviour of the crystallites composing the particles.

The orientation of irregular particles would also be expected to produce anisotropy of effective gas diffusion coefficients in extruded carbon rods. To investigate this phenomenon, effective diffusion coefficients, $D_{eff}$ ($H_2$–$N_2$), were determined on three commercial samples, all using coal-tar pitch as a binder: a lampblack gas baked at about 1,000° C. (*A*), a petroleum coke graphitized at about 2,500° C. (*B*), and a petroleum coke graphitized at about 3,000° C. (*C*). The apparatus and procedure described by Weisz and Prater[2] and us[3] were used. Samples ½ in. long by ½ in. in diameter were used; they were previously cut either parallel or perpendicular to the direction of extrusion from rods 2 in. long by ½ in. in diameter. The results on each sample, shown in Table 1, represent at least three different specimens, with the individual values duplicated within ± 5 per cent.

$D_{eff}$ ($H_2$–$N_2$) was calculated on the basis of the external geometrical length of the cylinder. If the pores in the solid are completely random in direction, the average length of travel of gas is shown by Wheeler[4] to be 1·41 times the external length of sample (tortuosity factor). However, if the particles composing the sample are oriented by extrusion, it is

Table 1. EFFECTIVE DIFFUSION COEFFICIENTS OF HYDROGEN–NITROGEN IN CARBON RODS PARALLEL AND PERPENDICULAR TO DIRECTION OF ROD EXTRUSION

| Sample | $D_{eff}$ (cm.²/sec., S.T.P.) | | Ratio of $D_{eff}$ |
|---|---|---|---|
| *A* | 0·049 | 0·038 | 1·29 |
| *B* | 0·044 | 0·039 | 1·13 |
| *C* | 0·088 | 0·053 | 1·66 |

seen that the assumption of randomness of pore direction is no longer valid. Parallel to the extrusion direction the tortuosity factor would be expected to approach more closely to 1 (perfect channelling)] the higher the degree of orientation. Conversely, the tortuosity factor perpendicular to the direction of extrusion would be expected to become progressively greater than 1·41 with increased orientation of the particles. Therefore, it is felt that the anisotropy of effective gas diffusion coefficients in the extruded carbon rods is primarily a result of differences in the tortuosity factor produced by particle orientation.

We thank Dr. P. B. Weisz and the Socony Mobil Laboratories for determining the effective diffusion coefficients.

## A Comparative Study of the Mode of Action of X-Rays and Alkylating Agents

PHARMACOLOGICAL and toxicological researches have shown that the effects of nitrogen mustard are strikingly similar to those of ionizing radiation[1]. On account of the great similarity shown by the effects of mustards to irradiation effect, the mustards have been termed 'radiomimetic poisons'[2]. The similarity, furthermore, was found also in the action on the viscosity of deoxyribonucleic acid[3]. On the other hand, Auerbach[4] found that the types of genetic change induced by mustard gas are in some respects different from those caused by X-rays, and suggested that the mode of action of the two agents is also different. Widner *et al.*[5] and Koller *et al.*[6] compared the cytological effects in normal and tumour cells, and found a significant difference which they attributed to the difference in the mode of action of these agents. The mechanism of the effect, however, seems to involve many obscure points and demands further investigation from various points of view.

I have succeeded in establishing resistant variants of the Yoshida ascites tumour to methyl-*bis*-(β-chlorethyl)-amine N-oxide, one of the alkylating agents, by passing tumour cells through animals treated with the agents (MBAO-resistant subline)[7]. These resistant variants were proved to be cross-resistant to the other three alkylating agents, namely, methyl-*bis*-(β-chlorethyl)-amine, tris-(β-chlorethyl)amine and tris-ethylen-imino-s-triazine, but not cros resistant to the unrelated agents, namely, 8-az guanine and colchicine[8]. It seemed, therefore, to l interesting to test whether the MBAO-resistant sul line is cross-resistant to X-rays or not. The suscep ibility to X-rays of tumour cells in the MBA resistant sublines was compared with that in th original sensitive strain of the Yoshida ascit tumour.

Rats of mixed breed and weighing about 100 gn were used, each receiving an intraperitoneal inocul tion of 0·02 c.c. of tumour ascites, containing abou $2 \times 10^6$ tumour cells. Half the animals in eac group (1,000 r. irradiation group, 200 r. irradiatio group and non-irradiated control group) were i oculated with tumour cells of the resistant sublin and the other half were inoculated with those of th sensitive strain. They showed 100 per cent suscept ibility to the tumour. The MBAO-s.c. resist ant subline[7,8] was used as a resistant subline. group of ten rats was exposed to a single dose 1,000 r. whole-body X-radiation, and another grou of sixteen rats to 200 r., on the fifth day after inocul tion with the tumour. The radiation factors were 160 kVp., 3 m.amp., half-value layer 1·02 mm. copper filter, 0·5 mm. copper plus 1·0 mm. aluminium focal skin distance, 30 cm.; and dosage rate 20 r./min Besides these X-radiation groups, another ten rat served as control material without X-radiation. Th sensitivity of the tumour cells to X-rays was judge by changes in the mitotic index (mitoses/2,000 tumou cells), which was calculated with Giemsa-staine smear preparations of the tumour ascites withdraw just before exposure to X-rays, and 1, 3, 6, 9, 12, 2 and 48 hr. after the end of exposure. The mitoti index of non-irradiated control animals was cal culated in the same way as in the irradiated animal The mean values of the mitotic index in each grou are represented in Fig. 1. All results were analyse statistically using the method of analysis of variance On the variation of mitotic index of non-irradiate control group, a significant difference was not foun between the MBAO-resistant subline and the origina sensitive strain ($P > 0.05$). Following exposure t X-radiation, as shown in Fig. 1, the mitotic cells i both resistant and sensitive strain decreased markedl

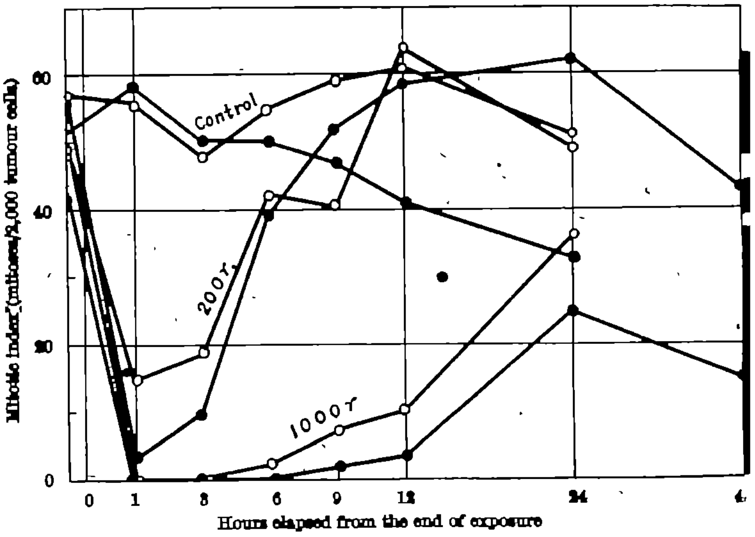

Fig. 1. Changes in the mitotic index following X-radiation
○——○, Original sensitive strain; ●——●, MBAO-resistant subline

number. In the group exposed to 1,000 r. X-diation the mitotic index recovered almost to the te it was before exposure about 24 hr. after the radiation, and after 200 r. irradiation it recovered the same way about 9 hr. after the irradiation. these irradiation experiments, the mitotic index the resistant subline was always markedly less an that of the sensitive strain, which was thus ill under the effect of irradiation. The difference tween these two lines was not significant statistically $> 0·05$) in animals given 1,000 r., but it was significant ($P < 0·01$) in animals given 200 r. In other ords, a significant difference on the sensitivity to -rays was not found after 1,000 r. irradiation, but ter 200 r. irradiation the MBAO-resistant subline as found to be more sensitive to X-rays than the BAO-sensitive strain. The fact that there was no gnificant difference of sensitivity after 1,000 r. radiation between the two lines may be attributed the striking effects of X-rays at that dosage-level.

Hence the tumour cells resistant to methyl-*bis*-(β-lorethyl)-amine N-oxide were not cross-resistant to -rays. Further, from these results it can be inrred that alkylating agents and X-rays are different their mode of action on the cell.

## Nature of Calcium Sulphate Gels in Ethylene Glycol

GILLE[1] has described the formation of a thick el by saturating ethylene glycol with gypsum, a$SO_4.2H_2O$, at 19° C., filtering carefully, and heatg the solution to 40° C., at which temperature, wing to its decreased solubility, the calcium sulphate recipitates, but in the form of a gel. Gypsum has a ructure[2] in which layers of water molecules alternate ith $CaSO_4$ layers, and Gille suggests that the last-entioned layers are preserved in the gel, but with hylene glycol substituted for the water, and causing n indefinite expansion.

Such an expansion would be similar to that of ontmorillonite, and we might expect it to be ssociated with a phenomenon of the same nature s 'interlamellar sorption' in that mineral[3].

These observations of Gille seemed of interest to s, in connexion with our studies on interlamellar welling and sorption, and we decided to investigate ille's gel by X-ray diffraction. We used the 'flat-ayer' technique[4], which is convenient for this type f study, since a little of the moist gel can be spread on filter paper, which is then mounted directly on the specimen holder. Some ordinary powder photographs (specimen in glass tube) were also made.

Photographs of the gel show haloes, as given by liquids or amorphous substances. If then the filter paper containing the gel is washed with methanol, ethanol or acetone, to remove the excess of ethylene glycol, a line at 17 A. appears, which does not disappear on treating with other organic liquids; but if one drop of water is placed on the filter paper, the 7 A. line characteristic of gypsum appears. The line at 17 A. remains on treatment with a mixture of one part of water and two of methanol; but a mixture two parts of water and one of methanol, or one of water and two of acetone, causes the gypsum line to reappear.

Because of too rapid heating, and possibly of other causes not yet clarified, the calcium sulphate may fail to form a gel, and be precipitated instead as a light sediment of fine particles. These particles give a line at 17 A., similar to that given by the gel washed with organic solvents.

It seems, therefore, that ethylene glycol can be substituted for the water molecules between the gypsum layers, and that the resulting $CaSO_4 - C_2H_4(OH)_2$ complexes are stable in the presence of many organic solvents, but unstable in the presence of water, which readily expels the glycol molecules. So far as our experience goes at present, therefore, the reaction with ethylene glycol is rather specific.

We tried to carry out the same preparation with $CaHPO_4.2H_2O$, which is isomorphous with gypsum[5], but without success. The presence of hydrogen ions perhaps causes more powerful bonding between the layers than in gypsum.

A fuller account of this work will be given elsewhere. Acknowledgment is made to the Consejo Superior de Investigaciones Científicas for a grant.

## Action of Complexes of the Zinc Group Metals on the Tail Protein of Bacteriophage $T_2r^+$

A SPECIFIC reaction has been found between complexes of the zinc group metals and the bacterial virus, $T_2r^+$. Zinc ions ($M/100$) do not inactivate $T_2r^+$, but if a variety of metal-complexing agents are added to a solution containing zinc nitrate and $T_2r^+$, the virus is rapidly and irreversibly inactivated. Identical reactions occur with cadmium ions. Mercuric mercury inactivates $T_2$ as the free ion as well as when present as a complex ion. Cyanide complexes of all three metals and iodide complexes of cadmium and mercuric mercury inactivate the virus. Inactivation also occurs when a number of amino-acids (such as $M/100$ glycine or glutamic acid) and pure proteins (such as trypsin or chymotrypsin at 2 mgm./ml.) are used as metal-complexing agents. Versene complexes of zinc, cadmium or mercuric mercury do not affect the virus.

The action of complexes of the zinc group metals is highly specific, since cyanide complexes of these metals inactivate only $T_2r+$ and $T_2r$ and do not inactivate $T_1$, $T_4r+$, $T_5$, $T_6r+$ and $T_7$, which invade the same host *E. coli* B. Further, cyanide complexes of other metals such as ferric and ferrous iron, silver, cobalt, nickel, and cuprous and cupric copper do not affect $T_2$.

Bacteriophage $T_2r+$ has been shown by antigenic analysis to contain at least two proteins which are usually designated as head and tail proteins[1]. The viral deoxyribonucleic acid is located largely within the head of the virus particle. Electron micrographs of $T_2r+$ inactivated by zinc or cadmium cyanide complexes show that the distal half of the virus tail is removed in the reaction (Fig. 1). The rate of viral inactivation is almost identical with the rate of appearance of virus particles with short tails (Fig. 2). $T_2r+$ inactivated in this manner loses its ability to attach itself to host cells, to kill host cells or to reproduce. These changes in the biological properties of the virus, together with the results of the electron micrographs, indicate that the metal complex is acting upon the tail protein of the virus particle.

The head of the inactivated virus particles always appears intact, but it may or may not contain deoxyribonucleic acid, depending upon the experimental conditions. From $p$H 6·0 to $p$H 7·5 there is little or no release of viral deoxyribonucleic acid from the inactivated virus particle (measured as the release of phosphorus-32 from labelled virus particles). However, from $p$H 7·75 to $p$H 9·0, up to 95 per cent of the deoxyribonucleic acid is released into the suspending medium within five minutes.

From the known dissociation constants for the four cadmium cyanide complexes, it is possible to compare the rate of inactivation of $T_2r+$ with the concentration of each complex. Using solutions of constant concentration of cadmium ions and varying concentration of cyanide ions, it was found that the inactivation-rate could be correlated only with the concentration of $Cd(CN)_3^-$. It appears that only $Cd(CN)_3^-$ inactivates $T_2$, whereas $Cd(CN)^+$, $Cd(CN)_2$ and $Cd(CN)_4^{=}$ do not affect $T_2r+$. The rate of the viral inactivation, measured conveniently a

$$\frac{1}{\text{time for 60 per cent } T_2 \text{ survival}},$$

increases logarithmically from $p$H 6·0 to $p$H 7·7, and does not increas further when the $p$H is raised to 8·7. When measure between 0° and 25° the $Q_{10}$ for the inactivatio reaction is 3·0. The fraction of $T_2r+$ inactivated i a given time is independent of the initial viru concentration.

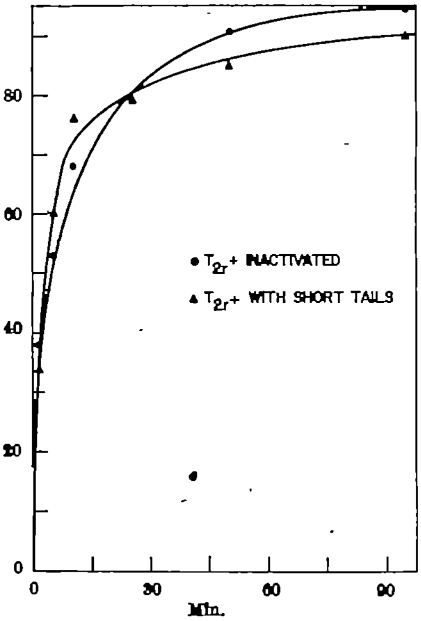

Fig. 2. The relationship between $T_2r+$ inactivation by cyanide complexes of Cd++ and the appearance of viral particles with short tails. Samples were taken at various times from the reaction mixture ($p$H 7·0, 25·0°, 0·01 *M* $Cd(NO_3)_2$, 0·033 *M* NaCN, initial $T_2$ was $10^{11}$/ml.) and assayed, and electron micrographs prepared in the usual manner. The fraction of virus particles with short tails was calculated from the electron micrographs

When *E. coli* B. is invaded by $T_2r+$ bacteriophag the virus attaches itself tail first to the cell and afterwards the viral deoxyribonucleic acid is introduc into the cell. Any uninjected deoxyribonucleic acid as well as the bulk of the vira protein which remains outside th cell, can be removed by stirrin in a Waring blendor[2]. Recen experiments have demonstrate that $T_2r+$ causes the release o nitrogenous materials from th bacterial cell wall, suggesting tha the virus makes a hole in the cel wall[3].

It has been possible to show tha after $T_2$ is adsorbed to the hos cell and presumably has penetrated the cell wall, the release o viral deoxyribonucleic acid from it protein covering and its passag into the cell requires the presenc of a polyvalent metal ion. Whe $T_2r+$ labelled with phosphorus-3 is added to susceptible host cells i nutrient broth + *M*/40 versen (which complexes all polyvalen anions) the virus is adsorbed and th host cells are killed. However, non of the bacteria produces phage, anc

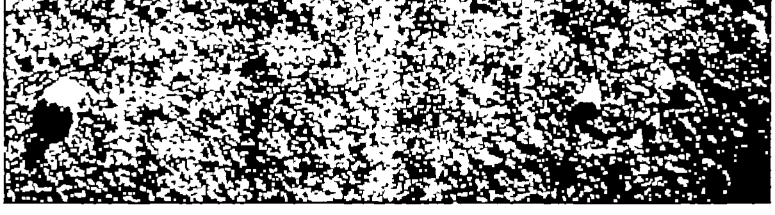

Fig. 1. Effect of 0·01 *M* zinc nitrate plus 0·033 *M* sodium cyanide on $T_2r+$ at $p$H 7·0 and 25°. After 1 hr. a sample was air-dried and shadowed with uranium. For comparison, the electron micrograph (× 8,000) shows a field containing one normal $T_2$ particle and one altered $T_2$ particle. The tail of the altered particle is one-half the normal length and is slightly thicker

y violent stirring of the cell-virus complex in a Varing blendor 90 per cent of the viral phosphorus-32 hat is, deoxyribonucleic acid) can be shaken off the ost cell. In the absence of versene, only 30 per ent of the viral deoxyribonucleic acid can be emoved from the host cell.

The similarity of the *in vitro* reaction between $T_2$ nd metal complexes and the reactions occurring uring invasion suggest that the mechanism by hich the tail of the virus is altered and the deoxyibonucleic acid is liberated from its protein covering uring virus-cell interaction involves the action of a etal complex.

This investigation was aided by grants from the Iational Foundation for Infantile Paralysis, Inc., nd the Dr. Wallace C. and Clara A. Abbott Memorial und of the University of Chicago.

## Direct Interaction between Copper Ions in the Molecules of Copper Acetate and Propionate

EXAMINATION of the magnetic properties[1] and also X-ray photographs[2] showed that the crystal of copper cetate consists of molecules, $Cu_2(CH_3COO)_4.2H_2O$, n which a direct type of metal-to-metal interaction might be anticipated. A similar metal-to-metal interction was proposed for copper propionate[3]. Recently, re have made a quantitative determination of the dichroism of microcrystals of copper formate, acetate nd propionate, demonstrating the existence of the opper-to-copper linkage in the crystal of the latter wo compounds, and absence of this linkage in the former.

Polarized absorption spectra in the visible and near ltra-violet of copper acetate were determined by suchida–Kobayashi's microscopic method[4]. Using he data of the crystal analysis[2], the components of he molecular absorption coefficients were estimated. The crystal shows in the above regions three absorpion bands, at 43, 80 and 100 × $10^{13}$ c./s. For the band at 43 × $10^{13}$ c./s., which is usually supposed o be due mainly to the copper atom in combination vith the ligands[5], absorption is much stronger with he electric vector along the plane containing four oxygen atoms around the copper atom than with the lectric vector along the direction binding two copper toms in a molecule. This relation agrees with the ule previously derived for the band of a similar kind with planar complexes of various metals[6]. The band t 80 × $10^{13}$ c./s. is of a new kind that has hitherto eldom been found, since most cupric complexes usually exhibit not more than one electronic absorpion band of moderate intensity in the visible and near ultra-violet[5]. Thus the appearance of the new band at 80 × $10^{13}$ c./s. might be taken as an indicaion of the linkage between two copper atoms. The present measurement indicates that for this band the lectric vector along the Cu–Cu axis is about 2·5 times s strongly absorbed as that perpendicular to this axis. This relation is different from the polarization characteristic for the absorption bands of typical planar complexes as well as for the 'copper band' at 43 × $10^{13}$ c./s. The reversal of the polarization property is in agreement with the assumption of the copper-to-copper linkage in $Cu_2(CH_3COO)_4.2H_2O$.

A similar measurement of dichroism was made with a crystal of copper propionate, $Cu(C_2H_5COO)_2.H_2O$. This exhibits a similar band of the new kind at 80 × $10^{13}$ c./s., in addition to a band at 43 × $10^{13}$ c./s., suggesting the existence of the copper-to-copper linkage. The polarization of the band at 80 × $10^{13}$ c./s. is found to be the reverse of that of the band at 43 × $10^{13}$ c./s. This relation, similar to that for copper acetate, also supports the above assumption.

The measurement shows that the crystal of copper formate tetrahydrate involving no copper-to-copper linkage[7] exhibits no band of the above kind at 80 × $10^{13}$ c./s. This also seems to support the metal-to-metal linkage in the crystals of copper acetate and propionate.

Copper acetate and propionate in alcohol or chloroform are found to show the band at 80 × $10^{13}$ c./s. It is concluded, therefore, that in the solution there should be such entities as $Cu_2(CH_3COO)_4X_2$ or $Cu_2(C_2H_5COO)_4X_2$ ($X = H_2O$, $C_2H_5OH$, or $CHCl_3$) in which the copper-to-copper linkage could exist.

## Chemiluminescence in the Decomposition of the Propyl Nitrates

THE decomposition of the alkyl nitrates is chemically complex, and studies of the spontaneous ignition of methyl and ethyl nitrates have shown that this complexity is associated with a variety of visually distinct modes of inflammation. Thus methyl nitrate[1–3] may undergo three different modes of decomposition: (1) slow decomposition unaccompanied by light; (2) chemiluminescent decomposition; and (3) explosive ignition. Sharp limits of pressure and temperature separate these different modes. Similar behaviour has been found for ethyl nitrate[1,2].

The inflammation of *n*- and *sec*-propyl nitrates has now been examined, and the critical pressure limits above which chemiluminescence and explosion occur have been measured over the temperature-range 240–340° C. These limits in a quartz reaction vessel, volume 350 cm.$^3$, surface to volume ratio 1·0 cm.$^{-1}$, are shown in Fig. 1.

*sec.*-Propyl nitrate shows the same two modes of inflammation as methyl nitrate. For example, at 260° C. when a pressure of 0·4 mm. is admitted to the reaction vessel, reaction is accompanied by an immediate faint bluish-white luminescence lasting about half a second. Above a pressure of 7·5 mm., the luminescence is succeeded after a very short induction period by explosive ignition. At low temperatures the two different modes of reaction are sharply differentiated. As the temperature is raised, so the pressure limits come together and the distinction between luminescence and explosion becomes less marked.

*n*-Propyl nitrate does not show two distinguishable modes of inflammation. At temperatures above 280° C., when the critical pressure limit is exceeded, decomposition is accompanied by an immediate, faint, brief glow of white light. The critical pressure limit resembles the chemiluminescence limit of the other nitrates rather than their explosive limit.

The decompositions of all these alkyl nitrates thus resemble the oxidations of many hydrocarbons, which show cool and blue flames, in addition to slow reaction and explosion. The emitter in these hydrocarbon flames is well known to be excited formaldehyde, and it has been suggested[1] that it is also the source of the luminescence in the decomposition of nitrates. This suggestion is supported by recent spectroscopic work on the decomposition flames of methyl[5] and ethyl[6] nitrates, from which formaldehyde emission has been found.

In the oxidation of hydrocarbons the origin of the excited formaldehyde is not known. An energy of about 75–80 kcal. mole$^{-1}$ is necessary; but it has been estimated[4] that fewer than ten excited formaldehyde molecules are involved for every million fuel molecules which react. It has been suggested[7] that the alkoxy radical $CH_3O\cdot$ is the precursor of $CH_2O^*$:

$$HO\cdot + CH_3O\cdot \rightarrow H_2O + CH_2O^* \quad \Delta H = -95 \text{ kcal.}$$

and recent data[8] on alkoxy radical thermochemistry show that this is energetically satisfactory. Other reactions between a methoxy radical and another radical may also be sufficiently exothermic.

In decomposition reactions of the type described here—of nitrates $RONO_2$, nitrites $RONO$, peroxides $ROOR'$ and hydroperoxides $ROOH$—luminescence is always associated[9] with the presence of alkox radicals generated in the initial fission; for exampl

$$C_3H_7ONO_2 \rightarrow C_3H_7O\cdot + NO_2$$

Further study of these alkoxy radicals, which a also known[10] to play an important part in hydr carbon oxidation, may provide the key to the origi of cool flames.

## Separation and Identification of Phenols b Paper Chromatography

THE application of paper chromatography to th qualitative separation of phenols and phenolic derivatives has been reported by a number of workers The methods described employ the one-dimensiona partition technique and they separate, with varyin degrees of efficiency, phenolic derivatives havin fairly pronounced structural differences.

Recent work in this laboratory[2] on the analysis c vitamin E has shown that a mixture of five tocopherols (differing only in methylation in the phenoli ring) can be separated completely by a two-dimensional technique. This technique consists of a first dimensional separation by adsorption chromatograph on zinc carbonate - impregnated paper, followed b second-dimensional reversed-phase partition chromatography on the same paper impregnated wit liquid paraffin. The tocopherols, in this system, separate as would be expecte from theoretical consideratio of the methylation relative t the phenolic hydroxy-group It was therefore of interest t see whether such a chromatographic system would be useful in separating closely related simple monohydri phenols.

A number of modification to the system were made Benzene was used as th developing solvent in th first dimension, since th lower phenols are not solubl enough in *cyclo*hexane. This in turn, required a heavie deposition of zinc carbonate in the paper than ha been used previously. I the second dimension, ethy

Table 1. $R$ AND $R_F$ VALUES OF PHENOLS

| 2-Ethyl-6-propyl-phenol | 0·82 | 0·10 |

oleate was used as the stationary phase and the oncentration of aqueous ethanol was changed.

Squares of Whatman No. 1 paper (25 cm. × 25 cm.) are immersed in a solution, prepared by suspending zinc carbonate (B.P.C. 40 gm.) and ammonium carbonate 30 gm.) in water (500 ml.) and adding 0·880 ammonia (200 ml.). The papers are hung in air for an hour, dried at 95° for three hours, and then ruled lightly in pencil, as shown in Fig. 1 (*AB* = *AE* = cm., *BC* = 4 cm.). The phenol or mixture of phenols (5–20 μgm. of each), dissolved in a suitable olvent, is applied to a prepared paper as a thin line along *FG*. The paper is then hung vertically in a ank from edge *HY*, with edge *AD* dipping in the solvent, and developed by the ascending method with dry benzene. The walls of the tank are lined with benzene-saturated filter paper. After three hours, he paper is removed and dried in air. The area *CDXY* is now immersed in a 5 per cent solution of ethyl oleate in light petroleum (40–60°), removed and allowed to dry. The solvent in the chamber s replaced by 40 per cent (v/v) aqueous ethanol and he paper hung in the tank with edge *AH* dipping n the solvent. The chromatogram is developed for sixteen hours, again by the ascending method. After drying, the paper is sprayed with any of the well-known phenol-spotting reagents, after which the ndividual phenols appear as a series of well-defined elliptical spots in the area *CDXY*.

Table 1 gives the $R$ values in the first dimension and $R_F$ values in the second dimension for a number of simple phenols. The results indicate a striking conformation between chromatographic behaviour and molecular structure. $R$ and $R_F$ values are both additive and constitutive functions, each being effected by contributions from carbon side-chains, according to the following rules. For each carbon atom in the side-chains, the $R$ value is increased by 0·03 and the $R_F$ value is decreased by 0·10; each substituent *ortho* to the hydroxy group further increases the $R$ value by 0·20 and decreases the $R_F$ value by 0·05. (Phenol itself has a slightly anomalous $R_F$ value and, in the $R_F$ series, *p*-cresol is better taken as the reference compound.) In the two examples given, simple branching in the side-chain seems to have an additional effect on the $R_F$ value, decreasing it by a further 0·07, but has no effect on the $R$ value.

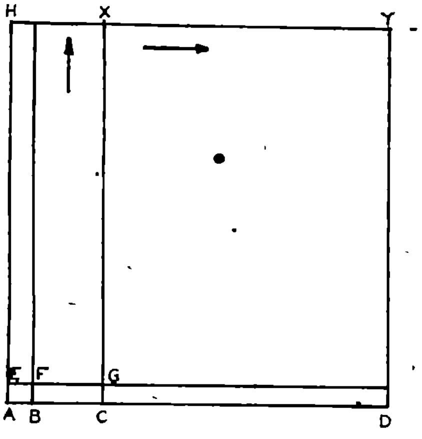

Fig. 1

From Table 1, it will be seen that many closely similar phenols are readily separated on the two-dimensional chromatogram, although others are not. In fact, the possibility of separation can be calculated.

The results are in general agreement with those already found on heavily substituted phenols such as the tocopherols[2], and it appears that the technique may have a more general usefulness in the isolation, separation and identification of phenol derivatives. With suitable modifications of the stationary and mobile phases, the method might be extended to more complex mono- and di-hydroxy derivatives, and it would be interesting to see whether the two-dimensional chromatographic behaviour of a highly complex phenol such as α-tocopherol could be completely correlated, through a series of chromatograms, with a simple substance such as, for example, *ortho*-cresol.

# Application of Paper Chromatography to Structural Problems in the Veratrum Alkaloid Group

IN a previous communication[1] we have described procedures for the separation, by paper chromatography, of the natural ester alkaloids derived from verabevine, cevagenine and cevine, as well as some partially synthetic esters of these alkamines. The most suitable solvent system proved to be chloroform on formamide-impregnated paper; detection was carried out with Dragendorff's reagent or by reaction with concentrated sulphuric acid.

A study of the effect of structure on the chromatographic behaviour of this group of compounds showed that the mobility is affected by the structure of the alkamine, the nature of the acid moiety, the number of ester groups and—very markedly—by the position of the esterified hydroxyl groups. In the case of the partially synthetic acyl derivatives, where the structure of the alkamine and the acylating agent are known, the remaining structural features to be determined are the number and position of the esterified hydroxyl groups.

As a result of the non-equivalence of the hydroxyl groups of the veratrum alkamines, the $R_M$ value of their derivatives is not a simple linear function of the number of free hydroxyl groups (cf., for example, ref. 2). Hence this relation cannot be used directly to determine the number of ester groupings; on the other hand, it becomes possible for the same reason to derive information as to the position of these esterified hydroxyl groups.

Since the hydroxyl groups in the veratrum alkamines form a number of diol groupings, we have attempted to exploit the reaction of such diol groupings with boric acid to determine the number of free glycol groups and hence in some cases the number and position of esterified hydroxyl groups. The same type of complex formation has previously been used, in the case of sugars[3-5], phenols and aromatic hydroxyacids[6], to decrease the rate of movement of suitably constituted compounds in paper chromatography.

In our procedure, the compound under examination is run in two parallel chromatograms with chloroform as the mobile phase on paper impregnated with formamide containing 5 per cent boric acid in one case, and with formamide alone in the other. Since the glycol–borate complexes are of a highly polar character, the rate of movement of compounds containing suitable glycol systems will be greatly decreased on the boric acid-impregnated paper. The difference in the $R_M$ values for the same compound in the two parallel experiments ($\Delta R_M$) will, moreover, give a direct indication of the number of free α-glycol systems present. Of the veratrum alkamines, veracevine and cevine contain three such systems (3 : 4, 12 : 14, and 16 : 17 or 17 : 20), cevagenine two (12 : 14, and 16 : 17 or 17 : 20). The examples recorded in Table 1 show that the presence of two glycol systems leads to $\Delta R_M$ values between 0·8 and 1·2 units, the presence of a single glycol grouping corresponds to a $\Delta R_M$ of 0·3–0·45, and in the absence of a free α-glycol system, the $R_M$ values are the same in presence and in absence of boric acid.

The change in $\Delta R_M$ upon acylation, upon partial methanolysis of polyester derivatives, etc., gives an indication of the number of glycol systems blocked by esterification of one or both hydroxyl groups involved. Similarly, information as to the presence of an ortho-ester grouping and, in the case of cevagenine, as to its position (ring *C* or ring *D*) may be readily obtained. Further possibilities of application are evident.

Table 1

| | Formamide | | Formamide–boric acid | | $\Delta R_M$ | No. of free glycol systems |
|---|---|---|---|---|---|---|
| | $R_F$ | $R_M$ | $R_F$ | $R_M$ | | |
| 3:4-Diacetylcevine | 0·55 | −0·08 | 0·09 | 1·0 | 1·08 | 2 |
| 3:16-Diacetylcevine | 0·14 | 0·78 | 0·03 | 1·6 | 0·82 | 2 |
| 3:*X*-Diacetylcevine* | 0·55 | −0·08 | 0·30 | 0·37 | 0·45 | 1 |
| 3:4:16-Triacetylcevine | 0·78 | −0·57 | 0·20 | 0·62 | 1·19 | 2 |
| 3:4:*X*-Triacetylcevine* | 0·55 | −0·08 | 0·30 | 0·37 | 0·45 | 1 |
| 3:4:16:*X*-Tetraacetylcevine | 0·78 | −0·57 | 0·64 | −0·25 | 0·32 | 1 |
| 3:4:16-Triacetylcevine-D-orthoacetate† | 0·62 | −0·2 | 0·59 | −0·17 | 0·03 | 0 |

* Chromatography and oxidation studies show that *X* is position 12 or 14.

† Developed with benzene–chloroform (7 : 3).

Table 2

| | Group constant *G* | | Position factor *a* |
|---|---|---|---|
| Acetyl | −0·7 | *C*.3 | 2 |
| α-Methylbutyryl | −1·2 | *C*.16 | 1 |
| Benzoyl | −1·2 | *C*.4 | 2·15* |
| Veratroyl | −1·35 | *C*.*X* | 0* |

* These values have so far only been verified for the acetyl deriv tives.

The results obtained by the above method are c interest with regard to the configuration of the glyc system in position 17 : 20. This configuration ha not yet been securely established[7], though Barto *et al.*[8] suggest that it is *trans*, on the grounds tha 3 : 4 : 16-triacetylcevine is inert toward lead tetr acetate oxidation. On the other hand, however, ou results indicate clearly (Table 1) that this glyc system is capable of complex formation with bor acid; past experience[9] would seem to suggest tha it is therefore more likely to have the *cis* configuratio

On the basis of the experimental material accum lated in this work, we have attempted to calculat the group constants, *G*, for the various acyl grou used to esterify the veratrum alkamines. Martin has shown that the introduction of a new group t a given fundamental molecule leads to a change i the partition coefficient (and hence in the $R_F$ an $R_M$ values) which is dependent on the nature of th group and the solvent system, but not on the natu of the fundamental molecule. As has been show above, in the case under consideration it is furth necessary to introduce factors expressing the effe of the position at which the change is made. Th we may write:

$$\log\left(\frac{1}{R_F} - 1\right) = R_M = Z + a_x G_1 + a_y G_2 + \ldots$$

where *Z* is the fundamental constant (for cevin $Z = 2{\cdot}9$), $G_1$, $G_2$ . . . are the group constants for th various acyl groupings, and $a_x$, $a_y$ . . . are the positio factors for the particular hydroxyl groups esterifie Some values for *G* and *a* are given in Table 2.

The use of this expression and the appropriat constants makes it possible to predict $R_M$ and henc also $R_F$ values for isomeric mono- and poly-esters c the veratrum alkamines. For the chromatographi detection and identification of esters of any furth acid it is, moreover, sufficient to determine exper mentally the $R_F$ value of a single alkamine ester c this acid.

A detailed account of this work will be publish elsewhere[11].

## Paper Chromatography of Steroid Glucuronosides and Sulphates

We wish to report the separation by paper chromatography of a number of steroid glucuronosides and sulphates. The composition of the three systems eported and the conjugates used are given in Table 1, ogether with the $R_F$ values noted in a representative xperiment. 10–50 gamma amounts of the free acids r their sodium salts in methanol were spotted on 2½-in. lengths of Whatman No. 1 paper and, after quilibration overnight at room temperature in aper-lined glass tanks, the mobile phase was added o the trough and descending chromatography was carried out for periods of 4–8 hr. Following chromatography, the papers were dried in a current of air at oom temperature, and the conjugates were detected y spraying with, or dipping in, 2–4 per cent phoshomolybdic acid in absolute ethanol followed by eating at 90°–100° C. for 5 min. Conjugate 2 was also detected by dipping in 15 per cent aqueous phosphoric acid, followed by heating at 90° C. for 0 min. and examination under ultra-violet light[1], or by dipping in a triphenyltetrazolium chloride reagent repared by combining immediately before use one olume of 2 per cent triphenyltetrazolium chloride in water with four volumes of 10 per cent sodium hydroxide in 60 per cent aqueous methanol.

In these experiments the ambient temperature varied from 23° to 33° C.; but in the course of a single experiment the temperature change usually did not exceed 3 degrees. Although $R_F$ values varied lightly with temperature, it was possible to use these ystems at temperatures as low as 4° C. and as high s 38° C.

System I has been used chiefly to separate conjugates 1 and 2 recovered from urine following the dministration of tetrahydrocortisone (pregnane-3α, 7α, 21-triol-11,20-dione)[2]. Substituting formic acid or acetic acid, as in system II, specifically increases he $R_F$ values of the sulphates and diminishes tailing. This system is the most useful one so far developed or separating the three sulphates. System III separates the several glucuronosides from one another nd from the sulphates, but does not separate completely the three members of the sulphate group. Fig. 1 illustrates the resolution of a mixture of onjugates 1, 2, 3, 4, 5 and 7 using system III. All three systems separate effectively conjugate 3 from onjugate 5 and, presumably, would separate other sulphates and glucuronosides having a common steroid moiety.

Table 1. $R_F$ Values of Steroid Conjugates chromatographed on Paper

Experiment 22A. Equilibration time, 14½ hr. at 29·7°–32·0° C. Running time, 5¼ hr. at 28·5°–29·7° C.

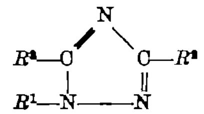
## Inhibition of Cholinesterases by 1 : 2 : 4-Triazoles

It has been repeatedly observed in my laboratory that workers, including non-smokers, manipulating 1 : 2 : 4-triazoles develop symptoms of light nicotine or physostigmine poisoning from time to time. Subsequent experiments have shown that some simple water-soluble 1 : 2 : 4-triazoles may act as inhibitors of cholinesterase activity.

Fresh brains of sheep or rabbit homogenized in 0·025 *M* sodium bicarbonate were used as sources of cholinesterase. Sheep brains were satisfactory, but experiments with rabbit brains could not be satisfactorily duplicated. The inhibitors tested were 3 : 5-dimethyl (I)-, 1 : 3 : 5-trimethyl (II)-, 3 : 5-dimethyl-1-phenyl (III)-, 3-ethyl-5-methyl-1-phenyl (IV)- and 5-ethyl-3-methyl-1-phenyl (V)-1 : 2 : 4-triazoles.



|  | $R^1$ | $R^2$ | $R^3$ |
|---|---|---|---|
| I : | H | Me | Me |
| II : | Me | Me | Me |
| III : | Ph | Me | Me |
| IV : | Ph | Et | Me |
| V : | Ph | Me | Et |

The cholinesterase activity was determined by the manometric method[1], using acetylcholine, acetyl-β-methylcholine and benzoylcholine chlorides as substrates. In all experiments a time-effect was noted: after an initial rise, the pressure decreased to a minimum after 10–20 min., after which the usual rise was observed, occasionally with slight fluctuation. A second 'wave' (usually after 60 min. or more) was observed when using rabbit brain with or without inhibiting triazoles, or sheep brain with (I) or (II) as inhibitors. Fluctuation of temperature, lack of saturation of the tested mixtures with carbon dioxide or insufficient equilibration were excluded as the causes of this phenomenon.

Triazoles (III), (IV) and (V) had the same effects; most experiments were carried out with (III), which was readily available[2]. The nature of the inhibition was ascertained by plotting inverse rates of carbon dioxide evolution against inverse substrate concentrations. Specific cholinesterase is competitively inhibited by (III) for substrate concentrations of 1–30 mgm. acetyl-β-methylcholine / 100 ml. and triazole/substrate ratios in the range of 0·01–0·05. At lower concentrations of triazole there is no significant effect; at higher concentrations the enzyme is slightly activated. In a similar range of concentrations of benzoylcholine and triazole/substrate ratios, (III) activates the unspecific cholinesterase; inactivation occurs at higher triazole concentrations. With acetylcholine as substrate the results were not consistent. In general, lower concentrations of triazole appear to activate, and higher concentrations inactivate, the enzyme system. As the cholinesterase activity of sheep brain is largely due to the specific cholinesterase, it is evident that a factor other than the specific and unspecific cholinesterases is involved in this case. The nature of this factor and the reason for the waves of cholinesterase activity in the stated cases are subjects of further studies.

I wish to thank students of my Department, particularly Mr. R. Naylor and Mr. P. W. Smith, for their assistance in checking some of the results.

## Double Reduction at the Rosy, or Pink, Locus in *Lythrum salicaria*

It is one of the peculiarities of tetrasomic inheritance, such as we have been investigating for some years past[1] in the purple loosestrife, *Lythrum salicaria*, that, for any two loci in homologous chromosomes, there are a large number of possible genotypes heterogenic at both loci, and therefore capable of throwing light on the process of genetic recombination. With only two alleles available at each locus, there are indeed nineteen such genotypes, and with the linked loci for short style and for pink, or rosy, flower colour, most of these have been obtained; although the six genotypes triplex for the domina Short gene have been inaccessible, owing to th illegitimacy of Short by Short matings.

For some years the only genotypes for which a large number of second backcross progenies had bee scored were bisimplex coupling, *RS/rs/rs/rs*, an bisimplex repulsion, *Rs/rS/rs/rs*. About 1¼ per cen of these appeared to come from gametes with tw dominant genes, *R*, so indicating[2] about 6 per cen double reduction at the *R* locus. The percentag however, was small, and in consequence a sma proportion of alien pollen carrying the *R* gene coul have seriously vitiated the estimated frequency. A the Short locus, for which the corresponding estima was about 2½ per cent, the danger of similar co tamination is obviated by the bar to illegitima pollination.

A few years ago, therefore, preparations were mad for a direct test of double reduction at the Ros locus by preparing triplex plants *rS/Rs/Rs/Rs*, an in 1954 progenies amounting to 2,057 plants wer grown, of which one only proved to be rosy, showin that the previous estimate was much too high. Th new estimate would be 0·2 per cent, if the exception plant was accepted as genuinely from the same see parent as the others, and, as any exception so rar as this is necessarily suspect, the true frequenc might be even less.

That the parents of these 2,000 plants were certain triplex at the Rosy locus has been demonstrated th year, 1955, by growing progenies of a hundred eac from a second backcross of sixteen purple Short plant from last year. If the parents were of the genotyp presumed, the expectation would be about six duple *RS/Rs/rs/rs*, and ten simplex in repulsion, *Rs/rS/rs/r* These were the only two genotypes recognized; ther were in fact four and eleven respectively, one progen being aberrant. The parents were evidently triple and the very low frequency of double reduction a the Rosy locus is confirmed.

The case illustrates well the efficacy of employin a second backcross for tetrasomic analysis. Wit the co-operation of Dr. O. H. Frankel at Canberr and Prof. H. N. Barber at Hobart, it is now hope that the difficulties of obtaining tetraploids triplex a the Short locus also may be overcome in a few year

## Monœcy and Incompatibility

It is customary when classifying breeding system in Angiosperms to make a clear distinction betwee three main mechanisms promoting outbreeding These are incompatibility in hermaphrodites, and separation of the sexes on the same plant (monœcy or on different plants (diœcy). With incompatibilit and diœcy outcrossing is obligatory. On the othe hand, separation of the sexes on monœcious plant merely decreases the probability of self-fertilization although this may be further avoided by difference in time of maturity of the two types of flower.

Clearly, however, wherever the sexes matur together on a monœcious plant, an incompatibility system could be of distinct advantage. This possibility not discussed in recent articles on incompatibility[1,2]. he following examples which I have found recorded ay serve to focus attention on this matter.

Cross- and self-incompatibility were found in *uphorbia cyparissias* by Muenscher[3], and it was oted by East[4] that "this experiment is the first to stablish that physiological incompatibility may exist a monoecious species". Clapper[5] showed that the apanese chestnut (*Castanea crenata*) and the Chinese estnut (*C. mollissima*) only rarely set fruit after lf-pollination. From a review of pollination experiments with *Hevea brasiliensis* (Euphorbiaceae)[6] it ppears that self- and cross-incompatibility occur, d that there may be reciprocal differences in seedtting. Whether this is an example of sporophytic ntrol of incompatibility remains to be seen.

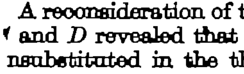
## New Flavones from *Pongamia pinnata* (L.) Merr.: Identification of Compound *D*

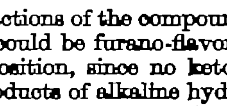
Two new furano-flavones (compounds *C* and *D*) ere reported by Row[1] from the root bark of *Pongamia innata* (L.) Merr., besides karanjin (I) and its ethylene dioxy derivative, named pongapin. From study of the alkaline degradation and other reactions, hey were regarded as isomeric with pongapin and aranjin respectively.

In an effort to identify these compounds, the imple linear isomer of karanjin, 3-methoxy-furano-: 6 : 2′ : 3′-flavone (II), was synthesized by Pavanram and Row[2]; but it was not identical with ompound *D*.

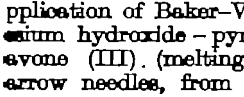
A reconsideration of the reactions of the compounds and *D* revealed that they could be furano-flavones nsubstituted in the third position, since no ketone ould be isolated from the products of alkaline hydroysis of these compounds. To test this possibility, -methoxy-furano-7 : 8 : 2′ : 3′-flavone (III) was obained synthetically from the O-benzoyl derivative of -hydroxy-5-acetyl-6-methoxy coumarone[3] by an pplication of Baker–Venkataraman migration (potsium hydroxide – pyridine method). The furanoavone (III) (melting point 180°; thin, fragile, arrow needles, from ethyl alcohol) depressed the elting point of compound *D* (melting point 177–79°) considerably (130–45°), thus establishing their non-identity.



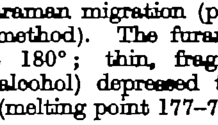
(I)



(II)



(III)



(IV)

The linear 5-methoxy-furano-7 : 6 : 2′ : 3′-flavone (IV) was also prepared from the benzoate of visnaginone by the Baker–Venkataraman method (using potassium hydroxide – pyridine). The furano-flavone (IV) (melting point 181–82°; broad rectangular prisms with a tendency to taper at one end) did not depress the melting point of compound *D* and was absolutely identical in its reactions.

The synthesis of 3′ : 4′-methylene dioxy derivative of the furano-flavone (III) was accomplished similarly. Its melting point was 263–64° and was different from compound *C* (melting point 232–33°). The synthesis of the isomeric 3′ : 4′-methylene dioxy derivative of the other furano-flavone (IV) is in progress.

With the identification of compound *D*, a new group of furano-flavones unsubstituted in the third position comes to light. Unlike karanjin (I), it belongs to the linear type. In this connexion, it is interesting to note that the only other naturally occurring furano-flavone so far reported is the unsubstituted furano-7 : 8 : 2′ : 3′-flavone (lanceolatin *B*), isolated from the roots of *Tephrosia lanceolata* Grab[4].

We are indebted to Prof. Alexander Schönberg, of the University of Cairo, for a gift of visnagin used in this investigation. We learn from him that the furano-flavone (IV) was also recently synthesized in his laboratories from visnaginone. Full details of the present investigation will be published elsewhere.

## Two Indo-Pacific Fishes, *Dasyatis uarnak* and *Upeneus moluccensis*, in the Eastern Mediterranean

DURING 1954, several specimens of *Dasyatis uarnak* (Forskål) were observed along the Mediterranean coast of Israel. They were caught by trawlers in depths of 15–40 fathoms. The captured fishes were usually big, with the disk often more than 100 cm. in diameter. One comparatively small specimen is preserved in the collection of the Sea Fisheries Research Station, Haifa. Its dimensions are: length of disk 440 mm., width of disk 470 mm., length of tail 1,215 mm.

The fish has not been recorded hitherto from the Mediterranean. It seems to be a common fish in the Indo-Pacific, and has been reported from the Suez Canal[1], through which the species has apparently passed to the Levant.

*Upeneus moluccensis* (Bleeker) is now common enough in the eastern Mediterranean to be of economic importance and has been mentioned several times under a wrong identification as *Mulloidichthys auriflamma* (Forskål)[2]. A careful examination of an extensive material from the Israeli coast and from Mersin, Turkey, revealed that all the fish belong to a single species, *U. moluccensis*. I have been able to compare the specimens from Israel with four paratypes of *U. moluccensis* lent me from the collection of the Rijksmuseum van Natuurlijke Historie, Leyden, and I can find no differences between them. Vomerine teeth, stated to characterize the genus *Upeneus*[1], are absent from both samples in specimens more than 65 mm. long, and this has led authors[3] to place it in another genus, in spite of the fact that the presence of palatine teeth should exclude it from *Mulloidichthys*.

Unlike other Indo-Pacific species recently recognized in the Mediterranean, *U. moluccensis* has never been recorded from the Red Sea; but if, as seems probable, it came through the Suez Canal, it must surely occur there.

A systematic analysis of these species will be published elsewhere. I am indebted to Dr. E. Trewavas for reading this manuscript and to Mr. N. B. Marshall and Dr. M. Boeseman for their help in securing a loan of the paratypes of *U. moluccensis*.

## Aeration of Coliform Cultures

PERIODICALLY, cultures of coliform organisms in simple synthetic medium (glucose–phosphate–ammonium salt) have failed to grow when aerated in this laboratory, contrary to experience in other towns. This culminated in a few weeks when such cultures refused to grow at all, so that the possible presence of poisons in the air was suspected. Consequently the air intake of the compressor was placed outside the laboratory buildings. The phenomenon persisted during the daylight hours but was eliminated at night time.

Two points now emerged: at the time, this area was suffering excessive and almost continuous rainfall, and the air intake was just above a mass of actively growing plants. This suggested that the trouble might be due to carbon dioxide deficiency in the atmosphere, which was being rectified by the metabolism of the plants when it was dark. Chemical investigation showed that in fact there was about five times as much carbon dioxide in this air at night as during the day, and about twice as much as in air taken from the laboratory during the day.

Various workers have noted the need for carbon dioxide by these organisms, probably to permit the formation of the $C_4$ dicarboxylic acids[1-5]. The addition of chemically prepared carbon dioxide or of extremely small quantities of succinic acid eliminated the phenomenon. From the work of Dagley and Hinshelwood[2], it can be calculated that a very small gas flame produces sufficient carbon dioxide to meet the requirements of a considerable number of cultures.

The air intake was now transferred to the space below a gas-operated incubator to ensure a sufficiency of carbon dioxide. The gas sucked in was purified by spraying as an oil–air emulsion, filtering and then passing through an efficient washing system filled with strong chromic acid. This removed dus alkaline vapours and oxidized volatile substance The gas was washed efficiently with bicarbonate sol tion to absorb all acid vapours and replace the with carbon dioxide. It then passed through bacteriological filter. The use of this air has eliminate the trouble completely.

The importance of adequate carbon dioxide h since been repeatedly emphasized: many phenomen being studied have been much more reproducible an in many cases the intrusion of lag phenomena eliminated. Such an example is the effect of phenol in lo concentration on one organism. Originally there w a progressive increase in observable lag and of th mean generation time with increase of phenol concentration; but with the new air supply no la phenomena are observed.

There may be many instances elsewhere whe fluctuating carbon dioxide content of the atmosphe and/or a bare average sufficiency are producin artefacts: here the problem became acute becau of a prevailing wind blowing from the open sea pa an extremely well-ventilated coastal laboratory.

## Resistance to Lymphomatosis in the Fowl i Relation to Reproduction

OVER the past twenty years, the feasibility breeding strains of fowls in which mortality fron lymphomatosis is reduced to negligible levels ha been demonstrated[1,2]. Many poultry breeders ar now developing resistant strains. If families resistan to this disease do not hatch as well as families tha are susceptible, as Coles and Underwood have stated the desirability of attempting to develop resistan stock may seem dubious. Accordingly, we hav examined our records for the past six years fo evidence of any such relationship.

In so doing, we have compared (as did Coles an Underwood) families of full sisters showing one o more deaths from lymphomatosis with families i which no females died of that disease during ou test period, which is from 42 to 500 days of age Since, in a later exposition of the same data[4] both fertility and hatchability of resistant familie were said to be lower than in susceptible familie we have considered both these important factor which influence the efficiency of reproduction.

Records for matings of proved sires in our *K* resistant strain of White Leghorns (Table 1) show the variation from year to year that is inevitable wit relatively small numbers. Over the whole period o six years, in families free of lymphomatosis, fertility (of their dams) was lower by 1·9 per cent; but hatchability was higher by 2·0 per cent, than in families losing one or more birds from that disease. Neither difference is significant. These data show no consistent relationship between resistance to lymphomatosis and efficiency of reproduction.

It is probable that this finding differs from that of Coles and Underwood because the data in Table 1 are restricted to dams' families comprising not less than ten tested daughters. Altogether there were ,685 such daughters, and in these the incidence of tal lymphomatosis during the test period was ·7 per cent. Among 726 females in the 44 dams' families that had one or more cases. the incidence was 9·8 per cent. With such low frequencies, small families have much less chance to show a single case f lymphomatosis than large ones. Since the smaller families result from poor reproduction and the larger ones from good reproduction, any division of the opulation into families that have either (*a*) no lymphomatosis or (*b*) one or more cases of it must throw most of the poor reproducers into the former class and the better reproducers into the latter one. Thus, in the birds considered by Coles and Underwood[3] the average size of family ranged in four years from 7·3 to 10·8 for those free of lymphomatosis, ut was 9·0 to 15·2 for those showing one or more cases[4]. Under such conditions, even if the incidence of lymphomatosis were as high as 15 or 20 per cent, ny apparent relationship between susceptibility to the disease and efficient reproduction is completely spurious.

Much of the error in such an analysis is removed by restricting the data to larger families. In those onsidered in Table 1, the average number of daughters per dam was 16·4 in families showing lymphomatosis and 15·8 in families that did not. All the error can be eliminated by using a better ype of analysis. The susceptibility of any family r group of birds to any disease is best measured. not by the presence or absence of a single case of that disease, but by the proportion of susceptible birds, that is, the incidence of the disease. Thus, in wo groups of 100 birds each, one comprising 20 mall families and the other five large ones, the ncidence of lymphomatosis should, *ceteris paribus* be about the same.

Among families[2] from proved sires in our *K*-esistant White Leghorns from 1949 until 1954 there were seven in which no daughters died of lymphmatosis. In each of the remaining nineteen sire amilies, the dams were separated into two classes as having hatchability either (*a*) above average for the pen, or (*b*) below that average. The incidence of lymphomatosis in the pullets hatched from these two groups was as shown in Table 2.

able 1. REPRODUCTION OF HENS PRODUCING FAMILIES WITH OR WITHOUT SUBSEQUENT LYMPHOMATOSIS

| Year | Dams | Eggs incubated | Fertile) (per cent) | Fertile eggs hatched (per cent) | Daughters tested |
|---|---|---|---|---|---|
| | *A*. Families with one or more deaths from lymphomatosis | | | | |
| 1949 | 15 | 579 | 97 | 88 | 217 |
| 1950 | 2 | 81 | 100 | 95 | 24 |
| 1951 | 11 | 441 | 89 | 86 | 160 |
| 1952 | 12 | 646 | 92 | 85 | 253 |
| 1953 | 1 | 40 | 100 | 93 | 25 |
| 1954 | 3 | 104 | 98 | 91 | 46 |
| Averages | | | 93·4 | 87 1 | |
| | *B*. Families with no deaths from lymphomatosis | | | | |
| 1949 | 10 | 381 | 94 | 91 | 157 |
| 1950 | 19 | 748 | 95 | 89 | 262 |
| 1951 | 29 | 1,143 | 90 | 91 | 444 |
| 1952 | 14 | 651 | 80 | 89 | 221 |
| 1953 | 27 | 1,100 | 92 | 86 | 397 |
| 1954 | 31 | 1,160 | 97 | 89 | 479 |
| Averages | | | 91·5 | 80 1 | |

Table 2

| | Dams | Daughters | Lymphomatosis (per cent) |
|---|---|---|---|
| Hatchability above average | 110 | 1,595 | 3 7 |
| Hatchability below average | 73 | 708 | 3 4 |

Dams below average are fewer than those above because, when hatchability is high, the distribution of dams with respect to it is skewed, and most hens below average depress that figure more than it can be raised by individual hens above it. The average numbers of daughters per dam in the two groups were 14·5 and 10·9, but, since the smaller families are grouped together, bias from that source is eliminated. Actually the two groups are not strictly comparable. The hens with hatchability below average included most of the oldest proved dams, which produced highly resistant daughters but (because of old age) fewer of them. Conversely, the hens above average included some not previously progeny-tested, but considered (from viability of their sisters) to be worth trying. These birds, being younger, reproduced well, but in some cases yielded rather susceptible families.

In spite of this, the two groups compared do not differ significantly in the incidence of lymphomatosis. It is clear from these data, as from those in Table 1, that resistance and susceptibility to lymphomatosis in the progeny are not related to the efficiency of reproduction in the dam.

## Relationship between Blood Factors *P* and *Q*

THE relationship between blood factors *P* and *Q* has been investigated by comparing an anti-*Q* agglutinin (Japanese) with several anti-*P* of human and animal origin.

The anti-*Q* has been used for agglutination tests only, while the *P* factor has been determined by absorption as well as by agglutination.

A total of 224 samples were tested. giving the following results :

| | *Q*+ | *Q*− | Total |
|---|---|---|---|
| *P*+ | 113 | 0 | 113 |
| *P*− | 0 | 111 | 111 |
| Total | 113 | 111 | 224 |

Cross-absorption experiments have not been carried out, as no discrepancies have been found.

Furthermore, the receptor strength of each positive sample was estimated by the strength of agglutination. In this respect, too, the reactions of anti-*Q* were found to parallel closely the reactions of anti-*P*.

Further details will be published elsewhere.

In our opinion, the result of the present investigation—until further irrefutable proof of the separate identity of the properties is found—justifies the assumption that *P* and *Q* are identical.

Our thanks are due to Prof. Tanemoto Furuhata, Tokyo, for a gift of anti-*Q*.

## A Caliper for measuring Photographs, X-Rays and Drawings

THERE is at present no instrument on the market suitable for measuring distances in photographs, X-rays or drawings both accurately and in considerable numbers. Our particular problem was to measure various dimensions of the human figure on 12 in. × 10 in. pictures of subjects photographed in the nude for studies of body-build. The measurements had to be accurate to 0·1 mm., and a large number of them had to be recorded. In this technique, known as photogrammetric anthropometry, needle-pointed calipers are used, so as to locate the precise point at which the edge of the body shades into the white background of the picture. Some form of enlargement of the scale of measurement other than a vernier, which is awkward to read and thus gives rise to too many reading errors, was clearly desirable. We first used calipers based on a scissors principle, with a magnification of scale of about × 5 due to the needle-pointed arms being shorter than the arms carrying the reading scale[1]. However, these proved unsatisfactory in practice due to the scale being on the chord rather than the arc of the opening circle, and because adjustment to remedy this varied from one instrument to another and was not entirely reliable.

A straight-bar design appeared to be better, and eventually the question of how to achieve the required scale enlargement was solved by the use of a dial gauge. The new instrument, made by British Indicators, Ltd., Sutton Road, St. Albans, Herts, is illustrated in Fig. 1. It rests flat on the photograph with the needle-tips adjusted so as just to clear the surface until tilted a fraction downward. The dial reads a total of 10 mm. in 0·1 mm. divisions and is linked to the right-hand needle point, which is moved by operating the thumbscrew at the far right-hand end. The left-hand needle point can be fixed at 1 cm. intervals up to 15 cm. by releasing the trigger seen underneath the left-hand bar, and moving the bar along until the desired figure appears in the round window at its right-hand end. This provides the coarse adjustment mechanism and enables the instrument to read in divisions of 0·1 mm. from zero up to as much as 15 cm. There is play of about 0·1 mm. in the thumbscrew mechanism, but this can be practically entirely obviated by arranging always to rack the dial in the same direction before taking the final reading.

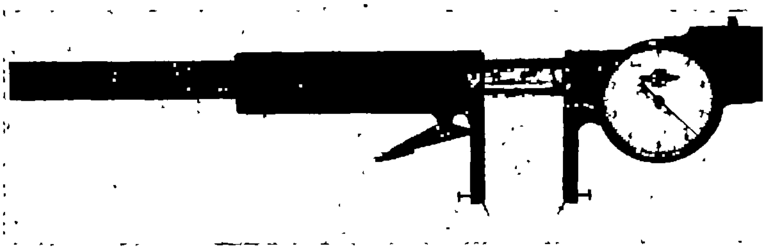

Fig 1

We have recently found this instrument useful for measuring the relative amounts of bone, muscle and fat along given diameters in X-rays of the legs and arms (see ref. 2), and in measuring the growth of epiphyses in serial X-rays of growing children. Hov ever, it is so much less tedious in operation tha conventional dividers that it seems likely to be use to research workers and engineers in a variet of fields.

## Removal of Mineral Nutrients from Tree Crowns by Rain

IN 1951, C. O. Tamm[1] gave figures for the miner nutrient composition of rain-water collected und three species of forest trees. M. G. Mes[2] has sinc published experimental work on the loss of phosphoru and other mineral elements from living leaves due t the influence of rain.

This communication reports the composition c rain-water collected under a thirty-year old plantatio of *Pinus radiata* D. Don in Whakarewarewa Fores Rotorua Conservancy.

The supply of nutrients to the soil in rain-water compared with the return contained in the litter-fa from the stand. The results in Table 1 cover th period November 26, 1954–June 2, 1955.

Table 1. NUTRIENT CONTENT OF RAIN-WATER AND LITTER COLLECT BENEATH *P. radiata*

| | Rain-fall (cm.) | Litter-fall (gm./m.²) | Nutrient return to soil (m. equiv./m.²) | | | | |
|---|---|---|---|---|---|---|---|
| | | | Ca | Mg | K | Na | P |
| Rain-water 30 yd. from trees | 68·7 | — | 1·3 | 1·4 | 2·2 | 23·4 | — |
| Rain-water beneath trees | 42·0 | — | 4·7 | 12·6 | 21·5 | 81·4 | 4·9 |
| Litter beneath trees | — | 252 | 61·6 | 21·2 | 16·5 | 10·4 | 24·6 |

It seems that when considering the return c mineral nutrients to the soil under *P. radiata*, bot litter-fall and rainfall must be taken into considera tion, since in the cases of potassium and sodiu a large proportion of the total return to the soil contained in the rainfall.

A fuller account of this work will be published at later date.

# FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

## Monday, December 19

Royal Geographical Society (at 1 Kensington Gore, London, .W.7), at 5 p.m.—Prof. S. W. Wooldridge and Miss E. M. J. Campbell: "Between Two Forests".

Institute of Metal Finishing (at the Northampton Polytechnic, t. John Street, London, E.C.1), at 6.15 p m.—Dr. A. E. Davies: Tin-Cadmium Alloy Plating".

## Tuesday, December 20

Royal Aeronautical Society (at 4 Hamilton Place, London, V.1), at 7 p.m.—Dr. N. A. de Bruyne: "Recent Advances in Aircraft Adhesives".

## Wednesday, December 21

Royal Meteorological Society (at 49 Cromwell Road, London, .W.7), at 5 p m.—Mr. C. H. B. Priestley: "Free and Forced Convection in the Atmosphere Near the Ground"; Mr. R. Anderson, Ir B. W. Boville and Mr. D. E. McClellan: "An Operational Frontal ontour Analysis Model".*

Royal Statistical Society (at the London School of Hygiene nd Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—rof. H. Wold: "Explanatory Approaches with Observational Data A Review of Ends and Means)".

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5 30 p.m.—Dr. J. M. Rowson: 'Comfrey (*Symphytum Officinale* L) Root: Its Anatomy and its Detection in Admixture with Chicory in Dandelion Coffee".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (male, single, with a university degree or diploma in horticulture and a sound knowledge of practical horticulture) in Horticulture—The Principal Agricultural Officer, Lancashire County Institute of Agriculture, Hutton, near Preston December 24).

Scientific Officers (with a first- or second-class honours degree n engineering, physics or mathematics or equivalent qualifications), and Assistant Experimental Officers (with at least G.C.E. advanced level) in mathematics or equivalent qualifications), in the Mechanical Engineering Research Laboratory (D.S.I.R.), East Kilbride, Glasgow, for work on fluid flow, heat-transfer, lubrication, materials and mechanisms—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, W.1, quoting C 886/5A (December 24)

Assistant (registered veterinary surgeon) in the Department of Veterinary Anatomy, Royal (Dick) School of Veterinary Studies—The Secretary, The University, Edinburgh (December 28).

Animal Pathologist (with a veterinary qualification) to take charge of the Department of Animal Pathology, Zoological Gardens, Regent's Park—The Director and Permanent Secretary, Zoological Society of London, Regent's Park, London, N.W.1 (December 31).

Assistant Lecturer in Psychology, with special reference to ndustrial and occupational psychology—The Registrar, The University, Hull (December 31).

Lecturer in the Department of Pathology—The Secretary, The University, Edinburgh (December 31).

Lecturer (with special qualifications in inorganic chemistry, ncluding experience in teaching from elementary level upwards) in Chemistry in St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (December 31).

Physiologist (with a university degree, preferably with physiology s a main subject, and between the ages of 21 and 28 years) in the General Post Office, to undertake field and laboratory studies on problems relating to factors affecting individual performance, and to work under the general direction of the Consultant Physiologist to he Post Office in London—P.O. Engineering Department (Stl/4), Alder House, Aldersgate Street, London, E.C.1 (December 31).

May and Baker Research Fellow (graduate in chemistry) to undertake research work under the direction of Prof. R. L Wain in organic chemistry in the fields of growth regulating substances or systematic fungicides—The Registrar, Wye College, near Ashford, Kent (January 7).

Physicist (with a first- or second-class honours degree and preferably have worked for at least two years in a radiotherapy department) o work in the Physics Department, but with special duties in the Radiotherapy Department—The Superintendent, Guy's Hospital, London, S.E.1 (January 7)

Biochemist (non-medical), Scientific Officer (Senior grade), for duties at the Central Laboratory, 51 Lisburn Road, Belfast—The Secretary, Northern Ireland Hospitals Authority, Victory Buildings, 44–46 Queen Street, Belfast (January 13)

Research Fellow in Mathematical Physics at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 Australia, January 15).

Veterinary Research Officer (with a veterinary qualification and experience in the organization and execution of field experiments, particularly with farm animals), to take an active part in research work, and a Biochemist (with a veterinary qualification or a good degree in chemistry or biochemistry, and experience in the field of animal nutrition and disease), to organize and initiate research, at the Animal Health Trust Farm Livestock Research Station, Stock, Essex—The Scientific Director, The Animal Health Trust, 14 Ashley Place, Westminster, London, S.W.1 (January 17).

Senior Lecturer or Lecturer in Clinical Pathology, Lecturer in Morbid Anatomy, and a Lecturer in Bacteriology in the Department of Pathology, University College of the West Indies—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (January 30).

Chair of Experimental Physics—The Registrar, The University, Liverpool (January 31).

Reader or Senior Lecturer in the Theory of Computing in the Department of Mathematics—The Registrar, The University, Manchester 13 (January 31).

Research Students/Fellows in the School of Physics—The Registrar, The University, Sydney, Australia (January 31)

Lecturer in Astronomy—The Registrar, The University, Manchester (February 28).

Lecturer (with special qualifications in stratigraphy) in Geology in St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (February 29).

Professor of Agriculture at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 15).

Agronomist, Senior Scientific Officer or Scientific Officer grade (with at least a second-class honours degree, and not less than two years appropriate postgraduate experience, and some experience of cocoa research or cocoa production), at the West African Cocoa Research Institute, Gold Coast, to design and conduct field experiments on cocoa, including yield, spacing, establishment, manurial, variety and other trials and to conduct experiments on fermentation and quality of cocoa—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting Ref. No BCD.197/200/05.

Assistant, Grade A (with a good degree) in Mathematics—Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham.

Assistant, Grade B (graduate in physics and preferably with experience in teaching and industry and a knowledge of some branch of applied physics), in the Physics Department, Sunderland Technical College—The Director of Education, 15 John Street, Sunderland

Biochemist or Chemist (with experience in routine biochemical techniques)—The Director, Department for Research in Industrial Medicine, London Hospital, E.1.

Chartered Librarian (with previous experience in a scientific or technical library)—The Secretary, Sir John Cass College, Jewry Street London, E.C.3.

Chemist or Physicist, Experimental Officer or Assistant Experimental Officer grade (preferably with a degree or H.N.C. in chemistry or physics, or at least H.S.C. (science) or equivalent), at a Ministry of Supply Experimental Establishment, Christchurch, Hants, to plan and carry out tests on properties of soils in connexion with their use for roads and airfields, and for investigation of soil stabilization techniques, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.442/5A/ED.

Electronics and Workshop Technician (with some practical experience in the maintenance of electronic or allied apparatus)—The Secretary, University College Hospital Medical School, University Street, London, W.C.1.

Entomologist (with a university degree in zoology (major subject being entomology), and preferably with postgraduate experience in mosquito control), in the Medical Department, H.M. Overseas Civil Service, Tanganyika, for field and laboratory entomological work with special reference to mosquitoes, and for the initiation and management of surveys and control work in urban centres and airports—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. No. BCD 117/8/024.

Forest Utilization Officer (with a university degree in either forestry or engineering, with postgraduate experience in forest engineering and/or in timber utilization) in Northern Rhodesia, to conduct research into the use of indigenous hardwood timbers by the Rhodesian copper mining industry, with particular attention to fungal decay and the preservative treatment of underground mining timbers, to assist sawmilling and logging firms on improving methods of logging, etc., and to assist in the development of wood-using industries—The Director of Recruitment, Colonial Office, Sanctuary Building, Great Smith Street, London, S.W.1, quoting BCD 61/3/02.

Lecturer in the Department of Electrical Engineering, Technical College, Bradford—The Director of Education, Town Hall, Bradford.

Lecturer (preferably with qualifications in electrical engineering) in Engineering in the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1.

Mathematician and Statistician (with a degree or equivalent qualification, and preferably some knowledge of economics) in the Operational Research Section of the Association in London, to continue a study of the productivity of steel rolling processes—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W 1, quoting "O.R.3".

Physicist (with a first- or second-class honours degree in physics and preferably with some research experience in optics or electronics) at the Royal Aircraft Establishment, Farnborough, for problems of photography from high speed, high altitude aircraft—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.450/5A/OB

Physicist (with a university degree in science and not less than three years experience as a physicist in a radiotherapy unit) in Salisbury Hospital, Rhodesia—The Secretary, Federation of Rhodesia and Nyasaland, Rhodesia House, 429 Strand, London, W.C.2

Principal Botanist, Principal or Senior Principal Scientific Officer grade (over 31, with at least a second-class honours degree in botany, with postgraduate training in cytology, genetics or plant physiology, and a good record of achievement in one or more of these branches, preferably in relation to tree crops), at the West African Cocoa Research Institute, Gold Coast, to organize, supervise, and take part in the work of the Botany Division, including cytology, genetics, plant breeding, physiology and general botany, with special reference to cocoa and its allies—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.197/200/011.

SCIENTIFIC OFFICER (with a first- or second-class honours degree or equivalent in physics or electrical engineering, and preferably with some electronics experience) at the Ministry of Supply Royal Aircraft Establishment, Aberporth, South Wales, for research and development on electronic instrumentation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.461/5A/KA.

SENIOR TECHNICIAN IN THE DEPARTMENT OF PHYSIOLOGY, University College, Ibadan—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1.

TECHNICAL ASSISTANT (preferably with experience of vacuum and high temperature equipment) IN THE GENERAL PHYSICS SECTION of the Physics Department, to assist in research on metal physics problems associated with the solidification processes in metals and with mechanical properties generally—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting G.P.1.

TECHNICIAN for research and general laboratory duties in the BOTANY DEPARTMENT, Dulwich, London, S.E.24, in the fields of biochemistry and microbiology—The Secretary, King's College, Strand, London, W.C.2 (Ref. 9491).

TECHNICIAN IN THE DEPARTMENT OF ANATOMY, Kitchener School of Medicine, University College of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1.

UNIVERSITY DEMONSTRATOR (member of the Royal College of Veterinary Surgeons) IN THE DEPARTMENT OF VETERINARY CLINICAL STUDIES, University of Cambridge—The Secretary, Appointments Committee of the Faculty of Medicine, Department of Experimental Medicine, Tennis Court Road, Cambridge.

# REPORTS and other PUBLICATIONS

**When lighting is limited...**

When available light is limited the laboratory worker will appreciate the extreme speed* of the new Kodak film, 'Tri-X'.

This speed has been achieved without corresponding increase in grain size. 'Tri-X' is therefore equally suitable for macrography and microscopy, for photography of living specimens and for recording work with very fast light-spots.

Colour sensitivity is evenly balanced throughout the spectrum; exposure latitude is generous. 'Tri-X' adds greatly to the scope of the camera in laboratory work. It is available in 35mm. miniature, 120 and 620 sizes.

**Kodak**
**'TRI-X' FILM**

EXPOSURE INDEXES: daylight 34° . . . 200
tungsten 33° . . . 160

**At an exposure of 1/25th sec., and with normal development, only about 0.0015 mcs. exposure is required to give a density of 0.1 above fog.*

**We have prepared a folder of data sheets giving information about 'Kodak' films of particular interest to laboratory workers. Please write for your copy.**

Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W.C 2

# ATOMIC ENERGY DEVELOPMENTS AND MAN-POWER PROBLEMS IN BRITAIN

WITHIN the limits set by security, the first annual report of the United Kingdom Atomic Energy Authority gives a reasonably full account of the Authority's activities (see p. 1193). Quite apart from the fact that, on the technical side, much of this has already been made known in other ways, the outstanding features of the report are, first, the way in which the rate of progress is set by the availability of skilled man-power, and second, the wide range of research on which both the civil and military programmes of the Authority are based. "Her Majesty's Government", states the report, "have never hesitated to furnish the money needed for buildings, plant and equipment for the atomic energy programme: material shortages have never been insuperable; but the difficulty of recruiting and retaining sufficient skilled scientists, engineers and craftsmen has been acute throughout the ten years of the project and shows no signs of becoming easier."

In setting this subject in the forefront of the report, the Authority recognizes that there is a national shortage of technological skill, and that it is in competition with industry (and notably with sections of industry that are themselves building up staff to enter the field of nuclear energy) for staff for its development programmes. More important still, it recognizes that the development of nuclear energy is unique in the variety of specialized skills which it demands. Since this demand is not at present being met, it is essential not merely to consider the steps already being taken to mitigate the shortage and the factors which may be responsible for the Authority's difficulty in recruitment, but also the distribution and use made of scientific and technical man-power in Great Britain as a whole.

The problem is, in fact, closely linked to that of the balance of the scientific effort of the country generally. The range of fundamental research, not only in physics but also in chemistry and metallurgy, which the efficient conduct of the Authority's development programmes urgently demands, is bound to suggest the possibility that there may be some distortion of that effort in other sciences besides physics, on which doubts have already been freely voiced. As the report notes, while fundamental work in physics, chemistry and metallurgy is carried out at the Authority's own establishments, extra-mural research at the universities and other institutions has made a major contribution to the work of the Research and Development Groups, while many research contracts have been placed with industrial firms. There is, however, nothing in the report which enables even an approximate estimate to be formed of the scale of this effort and its demands in terms of man-power, materials or finance relative to the nation's resources as a whole. Quite rightly, the report emphasizes the danger that even if the programmes are fulfilled according to the time-tables, the inadequacy of staff will lead to the skimping of details that will be the cause of operating troubles in future and possibly serious waste of resources. Even with adequate staff, there is always serious risk of premature development in the conditions under which the Authority operates.

It would be unreasonable to expect the Authority to discuss in this report the impact of its research programmes and contracts on academic or industrial research generally; but it is disappointing to find that the chapter on staff gives no figures which would enable the magnitude of the problem to be assessed. The report merely states that all but a handful of the senior staff in the former Department of Atomic Energy, and most of the industrial employees, have accepted employment under the Authority; that the staff taken over on August 1, 1954, was materially below the required level for the programmes then in hand; and that while the programmes have since been enlarged, there has been no corresponding increase in man-power. In the Industrial Group, in particular, recruitment of professional and scientific staff has done no more, during the past eighteen months, than keep pace with wastage; and the Authority is particularly disturbed at its difficulty in recruiting the younger engineers and technicians who are needed to form the base of the pyramid to-day and to provide the leaders in years to come.

Apart from the serious national shortage of most types of scientists and engineers and of many technical and craft grades, no reason is suggested for this failure; nor is any evidence adduced that the Authority is not recruiting a reasonable proportion of those available. It recognizes, indeed, that in attempting to recruit from outside the large number of senior staff required for its heavy new commitments, most of whom in normal expansion would be recruited from among its own staff, it is not easy to attract men who have long been settled in other employment and most of whom would sacrifice valuable pension rights on changing jobs. Here, perhaps, the lack of freedom of movement of the Authority, as compared with industry, in the matter of salaries may be a factor; and on this point the report notes that three salary bands have been established for managerial staff, within which officers will have their salaries assessed periodically according to individual responsibility and merit.

The report has already been used for urging a further considerable expansion in the number of students of science and technology. That may still be required, but there are questions to be asked and answered before such expansion is justified on the situation disclosed by this report. Some of these questions are indicated in the Haldane Memorial Lecture, "A Scientist In and Out of the Civil Service", which Sir Henry Tizard gave last March. Sir Henry is clearly one of those who have doubts as to whether in doubling the number of scientists and technologists we have increased in anything like the same proportion the number of really first-class minds. The report adopted by the Board of the Institute of Physics last July on the availability of places for physics students in universities and technical colleges, for example, emphasized that the most important factor determining the number of potential honours students of physics is that the course demands a degree of mathematical ability and a capacity to grasp difficult abstract concepts that are comparatively rare. It is highly probable that for a like reason the main obstacle to the expansion of the facilities for higher technological education in other sciences and in technology is the availability of students of adequate quality.

If this position holds, it is essential to give close consideration to the use which is made of the limited supply of outstanding talent. It follows, in the first place, that we cannot produce many more men capable, as Sir Henry Tizard puts it, of dealing with circumstances for which there is no direct precedent, whether in industry or in the public service, without diverting the interests of many young men from pure science or from other subjects. The sample survey of "Graduates' Jobs" recently made by Political and Economic Planning disclosed that, apart from the universities, manufacturing industry and the Scientific Civil Service already take much the highest proportion of first-class honours men, the Scientific Civil Service in fact taking 11 per cent as compared with 3·6 per cent entering the Civil Service. The Scientific Civil Service, moreover, lost almost 7 per cent of its recruits during the four years survey (compared with 10 per cent lost by industry).

Now although Sir Henry Tizard does not suggest that there is, as a rule, a lack of sympathy between scientists and administrators, he is concerned at a lack of understanding which will continue until far more administrators have had a scientific education. At present, he pointed out, on an average only one scientifically educated man enters the administrative Civil Service by competition each year. This is manifestly not enough to overcome the difference in outlook that exists between those who have had a scientific education and those who have not. This great need for more administrators who have had a broad scientific education is something to be kept in mind, equally with Sir Henry's remark about the ineffectiveness as an instrument of policy of a committee consisting solely of scientists, and the need for a leaven of hardened administrators, or their like, in considering the expansion of higher technological education. It is also worth remembering, in connexion with the recommendation by the standing committee of the Convocation of the University of London on the shortage of science teachers, that the University should consider jointly with other universities, so far as may be practicable, provision for an increase of science places of 60–100 per cent during the next five years for both school leavers and those of more mature age.

A fuller understanding and more sympathy between the scientist and the administrator in the Scientific Civil Service and in the public service generally could help to reduce the wastage indicated both by the P.E.P. inquiry and the annual report of the Atomic Energy Authority; indeed, it might well make the public service more attractive to the scientist. At the same time, it points to the need for a reasonable proportion of first-class minds on the administrative side as well as on the scientific and technical side. The need is one to be considered particularly in the plans for the expansion of the Imperial College of Science and Technology, of which Dr. Linstead recently spoke, and when graduates in science are no longer actively discouraged from the postgraduate study of some branch of technology.

Since it would seem that we cannot hope ever to produce enough scientists or technologists of the highest quality, and since also the cost per student in such a technological institution as the Imperial College is necessarily far higher than the average cost elsewhere in the universities, it is important that the target for expansion of technological education in Britain should not be set without some consideration of the possibilities of diminishing the demand by making sure that the fullest and wisest use is made of the services of the graduates to be trained in such institutions. It may well be uneconomic to attempt to use such institutions for the production of administrators with a broad scientific education, though they may help to produce scientists and engineers qualified to fill administrative positions. Here, however, devices in later life, such as the formation of a central scientific staff, engaged only on studying questions of policy under the immediate direction of the Advisory Council for Scientific Policy, to which young scientists could be seconded for a year or two from the research establishments, might serve better. As Sir Henry Tizard suggests, such a device would soon discover if the scientist possessed the necessary qualities for higher administration. It presupposes, however, that the research establishments are fully staffed, apart from the natural reluctance of a director to spare the men really worth transfer.

It cannot, therefore, be emphasized too firmly that every care must be taken in industry, as in the public services, to ensure that scientific and technological talent is really employed to the best advantage. Furthermore, granted the need for more first-class minds to study technology, and possibly also to some extent the sciences, the major need is for more men of the general practitioner type who will be dealing with conditions for which precedents exist. Most of these men will come from the colleges of technology or the universities, and a modicum of them may well prove suitable for administrative or managerial positions; but it is as well to remember that many leaders of industry have had no university training, and Sir Henry Tizard wondered whether all of them would have been better for a university education. On this point, Mr. M. L. Jacks has some wise words in his recent book, "The Education of Good Men", which point to the need for further inquiry as to the content of technological education before the lines on which it is to be expanded are rigidly set.

What is needed meanwhile, however, is a reasonable estimate of the demand for the ordinary graduate in science and technology, taking into account the wastage revealed by the P.E.P. inquiry. This should be supplemented by inquiry into the causes of that wastage and into the possibility of making better use of the services of the more outstanding men. Such inquiries might enable us to plan the expansion of technological education more economically and to make wiser use of our limited resources. It could also suggest ways in which both industry and the public services could be made more attractive to the scientist.

Any such estimate involves a survey of the national research effort, even if its present balance is accepted as reasonable. Whether an excessive proportion of that effort is already devoted to the Atomic Energy Authority, in spite of the vital importance of the Authority's developments for our economic position, as well as in national defence, remains for examination; it is a risk which might be more serious but for the broad basis of research on which those developments rest. That to some extent is a safeguard against excessive distortion between the sciences; though at the same time it increases the extent to which the Authority's programmes can affect the direction of fundamental research in the universities and elsewhere. When all due allowance is made for the limits set by secrecy requirements, those requirements, in this field at least, should be reconsidered in the light of the Geneva Conference last August, and it might well be that some adjustment might also facilitate recruitment of staff by the Authority. The scale of the effort now going into nuclear energy research and development in Britain, however, appears to be such that a broad picture of it in relation to the country's effort in research as a whole, both fundamental and applied, should be presented to Parliament and the nation in a way that would permit well-informed and constructive criticism, such as Sir Henry Tizard adumbrates, and at an early enough stage, when facts are being sorted out and the pointers to future policy are being formulated.

In this respect the first report of the Atomic Energy Authority clearly displays the need while supplying little information, even within its own field, towards enabling sound judgment to be formed or effective criticism made. In some respects it does not even indicate fully how important to Britain the early development of nuclear energy really is, and how urgent it is, from an economic point of view, that every effort should be made to utilize the advantages she at present possesses. None the less, that effort and its implications, both in respect of man-power and materials, must be seen in the perspective of the nation's resources and effort as a whole; otherwise development cannot proceed smoothly, because by drawing to itself an excessive proportion of man-power or other resources, advance has been checked in other fields of knowledge essential for the development of nuclear energy itself. The wise development of nuclear energy requires further surveys such as that now being made of the work of the Department of Scientific and Industrial Research. The Lord President of the Council carries no greater or more urgent responsibility than that of seeing that by such means, or in other ways, there is placed before Parliament sufficient information to enable the scientific and technical opinion of the country to satisfy itself that the research effort and the development work in this and other fields are in balance and in proportion with available resources.

---

# THEORY OF MOLECULAR VIBRATIONAL SPECTRA

## Molecular Vibrations

The Theory of Infrared and Raman Vibrational Spectra. By Prof. E. Bright Wilson, Jr., Prof. J. C. Decius and Prof. Paul C. Cross. Pp. xi+388. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 64s.

During the past twenty-five years the infra-red and Raman vibrational spectra of a great number of organic and inorganic molecules have been measured. Only a very few of these have been considered theoretically in any detail. This is partly due to the difficulties involved, but partly due also, I think, to the fact that there has been no book presenting fully in one place the mathematical theory of molecular vibrations. This book by Profs. E. B. Wilson, J. C. Decius and P. C. Cross is therefore a much-needed one. It is particularly valuable that one of the authors should be Prof. Wilson, for, during recent years, he, together with his students, has contributed more than anyone else to the theory of molecular vibrations and to devising methods of handling the mathematical and numerical problems arising therefrom.

The approach presented in the book is, of course, necessarily mathematical, and to most chemists the mathematics is not easy, for it involves procedures, such as matrix algebra, with which many are unfamiliar. However, in this respect, the authors have made great efforts to help such readers. For example, there is an appendix of ten pages summarizing matrix notation and those procedures involved in the application of matrix methods to the problems of molecular vibrations. Also, several examples of the construction of the various types of matrix that have to be used are given in the text so that the reader can see how it is done and can then test his own skill. This is so much less time-consuming than learning from the appropriate mathematics book, for the information obtained has then to be adapted to the problem in hand. Here it is presented in relation to the vibration problem. It is not possible for the authors to make all the mathematics involved easy for those who have little training in that subject, since many of the arguments and processes are difficult and complex. However, they do go to considerable lengths to see that, between the covers of this book, there is a great deal of help regarding the mathematical methods involved. It seems to me that they might perhaps have included a further brief appendix on vector notation, which would have been helpful to those finding the beginning of Chapter 4 unfamiliar.

Examining the contents in more detail, the first two chapters provide a valuable introduction to the theory of molecular vibrations and normal co-ordinates. The third considers the application of wave mechanics to this subject, a consideration of Raman and infra-red spectral intensities being introduced here. The next three chapters present the methods that have been devised, largely by Prof. Wilson and his students, for handling the mathematical problems and for making use of symmetry and group theory. In Chapter 7 selection rules and intensities are considered in more detail, and, in the following chapter, the authors discuss the form of the molecular potential-energy function together with information that can be obtained about it. This is followed by a chapter which describes the methods, both numerical and instrumental, which can be used for solving the equations that are obtained as a result of the procedures previously described. Finally, there is a most useful chapter which presents a sample vibrational analysis of the molecule of benzene. The inclusion of this chapter is a very happy idea, for it enables the reader who is not a mathematician to test whether he has learnt correctly the lessons of the earlier chapters. Another excellent feature of the book is the long list of appendixes which occupy about a hundred pages. These contain much extremely useful information which, had it been included in the body of the book, would have been distracting to the development of the ideas presented there. The subject and author indexes are good, and the table of contents at the beginning is very complete. It is easy, therefore, to find one's way to the page or section one wants.

This book certainly meets a great need and meets it most successfully. For many of those who want to, and should, read it, it will not be an easy book; but it does provide the easiest and quickest route to acquiring skill in handling the mathematics of molecular vibrations, a skill which many are interested in obtaining. J. W. Linnett

# NIELS BOHR BIRTHDAY ESSAYS

## Niels Bohr and the Development of Physics

Essays dedicated to Niels Bohr on the Occasion of his Seventieth Birthday. Edited by W. Pauli, with the assistance of L. Rosenfeld and V. Weisskopf. Pp. vii+195. (London: Pergamon Press, Ltd., 1955.) 30s. net.

THE custom in many countries of honouring an eminent scientist by dedicating to him a birthday volume, or an issue of a learned journal, is an agreeable one which has been rarely, if ever, practised in Great Britain. The present book of essays pays tribute to a man who, both by his achievements and by his leadership, has profoundly influenced the development of modern physics. Niels Bohr was awarded the Nobel Prize for Physics in 1922 for "investigations on the structure of atoms and of the radiation emanating from them"; and this work, which taught us the theory of the hydrogen spectrum, stood only at the beginning of a series of major contributions to atomic and nuclear physics. The chapters of this book have been selected by the editors to represent some of the problems with which Bohr has been concerned; they have been written by well-known physicists who at one time or another worked with him in Copenhagen or elsewhere.

The essay by Sir Charles Darwin on the discovery of atomic number traces the development of atomic theory through the nineteenth century and up to the discovery of the nucleus by Rutherford in Manchester in 1911. The theory of the hydrogen atom followed soon after Bohr's arrival in Manchester at about that time. The following years were taken up with further developments of the Bohr theory; but at the same time attention was being directed to the fundamental principles of quantum mechanics. W. Heisenberg, in his essay on the development of the interpretation of the quantum theory, shows how, following the work of Bohr, Kramers and Slater, many serious attempts have been made (and are still being made) to clarify the relationship between the production, absorption and propagation of quanta and of material particles. W. Pauli, writing on the exclusion principle, Lorentz group and reflexion of space-time and charge, discusses the connexion between spin and statistics in a way which illustrates the fact that rigorous mathematical analysis and physical insight should be complementary, as indeed they are in the work of Bohr. Then follow two papers on field theory: on the quantum theory of fields, by L. Landau; and on quantum electrodynamics, by L. Rosenfeld. They discuss the present state of development of a subject which has its roots in Bohr's correspondence principle, and which is at present actively engaging the attention of a great many theoretical physicists. O. Klein contributes an article on quantum theory and relativity, in which the relation between these two great physical theories of the twentieth century is treated and which ends with an interesting reminiscence of an encounter between Bohr and Einstein.

The remaining essays come, like the first of the volume, nearer to experimental physics. H. B. G. Casimir, writing on the theory of superconductivity, reminds us that Bohr's thesis in the University of Copenhagen was on the subject of electrons in metals. F. L. Friedman and V. F. Weisskopf contribute a very clear account of the compound nucleus, which has been accepted as one of the basic concepts of the theory of nuclear reactions ever since it was suggested by Bohr in 1936. Finally, the articles by J. A. Wheeler on nuclear fission and nuclear stability, and by J. Lindhard on the passage through matter of swift charged particles, touch on subjects which, although of a less fundamental character than the basis of quantum theory, have been treated by Bohr with no less understanding and insight.

Most of the chapters in this volume are brief but expert essays; several of them include personal memories. Taken together in the light of their common theme, they are a record of remarkable achievement. The editors and publisher are to be congratulated on having made such a record available. W. E. Burcham

# UNITED STATES PHARMACOPEIA

## The Pharmacopeia of the United States of America

Fifteenth Revision. (U.S.P. 15.) Pp. lii+1178. (New York: United States Pharmacopeial Convention, Inc., 1955. Distributed by Mack Publishing Company, Easton, Pa.) 10 dollars.

THE first "United States Pharmacopeia" appeared in 1820; the fifteenth revision follows the fourteenth after an interval of five years. The Committee of Revision has been enlarged, and the full-time staff is now housed in permanent headquarters at 46 Park Avenue, New York City, working under a new director—Dr. Lloyd C. Miller. The Committee of

Revision contains about sixty members and, as the preface puts it, "the organization plan has been thoroughly revamped". There are ten subcommittees, one of which, the Subcommittee on Scope, is advised by fifteen panels, the members of which are not necessarily members of the Committee of Revision. There are also eighteen additional committees, advisory boards and panels dealing with such problems as insulin, steroids, vitamins, hyaluronidase, pyrogens and style.

Latin titles have been dropped practically entirely, and this is a good thing because a large proportion of the Latin names used for describing drugs have been invented during recent years and invented differently in different countries. Pharmaceutical Latin is no longer an international language. It is satisfactory to see that the titles of new articles are generally the non-proprietary names recommended by the United Nations World Health Organization, but sad that so many of these names are far too long. In each monograph there is a statement of category which indicates, often in a single word, the main use or action of the drug described. This new and original feature will be useful to those who are puzzled by some of the new names. The abbreviation mcg. is used to mean microgram; and this is unlikely to be generally accepted because a logical application of traditional usage suggests that it means millicentigram.

A new section is devoted to the mathematical procedures used in connexion with biological assays. This is by no means a faithful copy of the similar section which appeared in the last "British Pharmacopœia". It is more complicated and less general in its scope, being specially adapted to the methods of assay which actually appear in the "United States Pharmacopeia". The methods used by the microbiologists, however, vary among themselves so much in arbitrary details that it would be impossible to provide formulæ for all of them, and the final interpretation of the results often depends on the actual drawing of the curve of best fit. There is nothing about probits because probits are not used in any official method of assay. This section will undoubtedly be useful to those who have to fulfil the official requirements laid down in this book.

The Committee of Revision must be warmly congratulated on the successful completion of a gigantic task. Necessary expenses are financed by the sale of the book, and the whole project is a fine example of what can be accomplished by unofficial enterprise aided by unselfish public spirit. J. H. Gaddum

# THE LETTERS OF JOHANN BERNOULLI

Der Briefwechsel von Johann Bernoulli

Herausgegeben von der Naturforschenden Gesellschaft in Basel. Band 1. Pp. 532. (Basel: Birkhauser Verlag, 1955.) 60 francs. 60 D. marks.

THE city of Basle produced, in about a century, twelve mathematicians of significance, of whom eight were bearers of the name Bernoulli. Four of the twelve were really distinguished mathematicians; these were the immortal Euler and three of the Bernoullis—Johann, his elder brother Jakob and his son Daniel. The publication of the complete works of Euler was undertaken more than forty years ago; now a similar publication of the works of the Bernoullis is being begun. A complete publication of the works of the greater Bernoullis is being attempted, except that letters which have been printed before—for example, in the complete works of Leibniz and Euler—are excluded; a selection will also be given of the works of the lesser Bernoullis and of J. Hermann, a pupil of Jakob. The whole is expected to run to about twenty-two volumes.

The first volume is devoted to correspondence to and from Johann Bernoulli. It covers the period from 1690 to 1706, when Johann succeeded his brother Jakob as professor of mathematics at Basle on the death of the latter. The first eighty pages of the volume are an editor's foreword to the whole series. This includes historical notes, in particular a most interesting account of the disappearance of most of the Bernoulli papers from sight about the year 1800, and their rediscovery after a long search nearly a hundred years later. This account reads like a detective story, with most of the mathematical detectives following their clues with an acumen worthy of Dr. Watson rather than of Sherlock Holmes.

The letters published fall into three groups. First come four letters from Johann to Jakob, the only ones between them known to survive. The rest were apparently destroyed by Johann's descendants out of filial piety, because they depicted too well the quarrel between the brothers. The four remaining are, however, enough to illustrate why the quarrel arose. They show Johann as a person very conscious of being cleverer than Jakob, who had taught him mathematics, and unwilling to allow in others claims for priority which he always expected to be conceded to himself.

The second group is of letters to and from l'Hôpital (mainly from him). The editor makes it clear, in a lengthy introductory note, that these letters, together with lessons earlier given to l'Hôpital in Paris by Johann, were in fact the main source of l'Hôpital's celebrated book on the calculus: "Analyse des infiniment petits". The essentials of the book were provided by Johann, who was for some years a pensioner of l'Hôpital; the latter's chief contribution was the clarity with which the ideas were expressed. The letters are mainly concerned with the application of the calculus to geometry; they include Johann's discovery of the rule, usually called l'Hôpital's, for the evaluation of indeterminate forms of the type 0/0. During his lifetime Johann claimed that much of l'Hôpital's work was really his own, quoted without acknowledgment. Johann's known predilection for imputing plagiarism to others has led earlier historians to be scornful of his claims; but in this instance they appear to have been justified.

These groups of letters are in French; the third group is a heterogeneous set, in French, German, Latin and Dutch. It has little mathematical interest, but some historical. It is mainly concerned with Johann's tenure of a chair of mathematics in Groningen, 1695–1705, and with negotiations for his transfer to Utrecht. One is reminded of the many-sided character of learning in those days on first reading a letter on a medical subject (Johann was originally trained as a doctor) and then finding an epigram in Latin verse addressed to him, to which he replies in similar verse.

The whole has been very carefully edited, with copious notes and indexing. The volume is beautifully produced and will form a valuable addition to any library. T. G. Cowling

# SORTING MOLECULES

AT the British Association meeting in Bristol, Section B (Chemistry) arranged a session, held on September 5, at which the subject of "Sorting Molecules" was discussed. An introduction was given by the chairman, Prof. W. Baker (Bristol), who referred to the importance of sorting molecules by physical processes, and to the earliest methods of crystallization, distillation and sublimation. The first two of these are still by far the most used, and reference was made by Prof. Baker to fractionating columns, distillation in vacua, molecular stills and falling-film evaporators. The potentialities of co-distillation with non-aqueous liquids have been little explored. Other methods of sorting molecules are selective surface adsorption, gaseous diffusion, sedimentation by means of the ultracentrifuge, electrophoresis, and the method of distribution between two incompletely miscible solvents which has reached a high state of perfection in the Craig counter-current distribution machine.

During recent years the methods of chromatography have become commonplace in almost every chemical laboratory. In its various forms, there are elution and displacement chromatography on columns of adsorbents, or on liquid phases suspended on solids or paper. The extension of adsorption and displacement chromatography to vapours is the technique of gas chromatography, and its delicacy and rapidity mark it as perhaps the most important recent advance in analytical procedures. A further method for sorting molecules, depending on molecular size and shape only, is by means of inclusion compounds, in which a 'guest' molecule is included in cavities or tunnels in the crystal of a 'host' molecule. These holes show a remarkable selectivity in accommodating some molecules and rejecting others, and may even be capable of sorting right- and left-handed forms of the same molecule. A related method is the use of a semi-permeable membrane in dialysis; but a much more selective method is to use as a sieve a crystal lattice containing holes of molecular dimensions which can be penetrated by molecules of suitable size and shape.

In the first paper, which was on "Gas Chromatography", Dr. F. H. Pollard (Bristol) said that some indication of the importance of this new method has been the speed with which many industrial laboratories have adopted and developed this technique. The principle used in gas chromatography consists in causing each substance in a mixture to migrate at a different rate through a column of powdered material. This is achieved by one of two methods: adsorption chromatography, that is, differential adsorption on a solid such as charcoal or alumina; or gas–liquid partition chromatography, that is, differential partition of the vapours between a liquid phase held on an inert powder and a gas such as nitrogen or hydrogen flowing over the solid. For example, a mixture of hydrocarbons is admitted to the top of a column of material, and a stream of nitrogen is then passed downwards through the column, carrying the hydrocarbons with it. If the conditions of operation have been arranged correctly, the components of the mixture will leave the column one by one, and their detection as separated components depends mainly upon instruments which record differences in the physical properties of the gas stream as it emerges from the column. The two physical properties which have been extensively used for this purpose are thermal conductivity and density. Automatic recording can be readily employed, and the emergence of the different components of a mixture is indicated by a series of peaks automatically recorded on paper. From such records the individual components of a mixture can be identified and quantitatively estimated. The time required for the complete analysis can be as little as twenty minutes. For mixtures such as those of fatty acids, automatic titration equipment has been used, and for others simple volume measurements have been employed. At the meeting, demonstrations of separations using the thermal conductivity cell as a method of detection were given on two different commercial machines, arranged by Dr. B. W. Bradford (Imperial Chemical Industries, Ltd., Billingham), and a demonstration of the gas density balance was given by Mr. D. H. Desty (Research Department, British Petroleum Co.) through the courtesy of Dr. S. F. Birch.

Adsorption chromatography has been used for the separation of hydrocarbons and a wide range of organic compounds, using either frontal analysis, displacement analysis, or elution analysis on either carbon or silica gel. Janak has devised a very simple form of apparatus in which a 1–3 ml. sample is passed through a column in a stream of carbon dioxide and the volumes of the separated components measured in an azotometer over potassium hydroxide solution. This method has been applied to rare gases as well as to many organic compounds.

The development of gas–liquid partition chromatography in 1952 by James and Martin marked a great advance in technique which has led to a large number of applications. Since the first separation of milligram amounts of fatty acids on a column of kieselguhr at 137° C. carrying as static phase a mixture of liquid silicone and stearic acid, there have been extensive developments for the separation of aliphatic amines, pyridine homologues, methyl esters of higher fatty acids, halogenated hydrocarbons, organic nitrates and nitrites, and boron hydrides. Higher-temperature columns are being developed, and have already been used for $C_{12}$—$C_{22}$ fatty-acid esters. Methods have been described for identifying unknown organic compounds by comparing retention volumes on two or more columns containing different static phases, which allow of different extents of interaction between the substance and the static phase. This technique of analysis has been applied to problems in chemical kinetics; for example, thermal decomposition of ethyl nitrate; studies in air pollution; identifying polymers by analysing pyrolysis products; the preparation of radiochemically labelled fine chemicals; and the large-scale separation of highly fluorinated organic compounds.

In the second paper at the meeting, Mr. H. M. Powell (Oxford) considered the problem of "Sorting Molecules by Shape and Size". Several methods, in particular those of X-ray crystallography, reveal that different substances are made up of molecules or other groupings of atoms. Their shapes and sizes may be accurately measured, and there is the possibility of separating molecules by sorting, after observation of their shapes and sizes.

Some substances have very large molecules; but many molecules contain only a few atoms, and have no dimension exceeding a ten-millionth of an inch. It is not, therefore, a simple matter to sort molecules, and if they are to be separated by their shapes it must be by something of the same order of size as the molecules themselves—that is, it must be done by other molecules or atoms.

Whenever a crystal grows from a mixture of substances as in a solution, it is automatically separating some particles from others; the crystal grows by adding particles of the same kind. It may not completely reject all others because, within limits, lattices may tolerate other atoms or molecules which are not too dissimilar.

Some substances are able to form crystalline inclusion compounds. The atoms of one component build up a structure which has in it cavities large enough to contain molecules of a second substance. Structurally there are two main types: either the cavities are effectively closed; or they are open, long channels. These structures sort molecules by size and shape because they can contain only those molecules which are of suitable size. Closed cavities may contain molecules up to certain critical sizes and will exclude longer ones, whereas channel structures may include both long and short molecules, but will not take in the shortest ones because the van der Waals interaction between enclosed and enclosing materials is too weak.

Urea adducts form a honeycomb-like structure with long molecules in the channels, and have been used to separate straight-chain from branched-chain aliphatic molecules which are too broad. Separations with up to 95 per cent efficiency have been reported. The method has been applied to compounds with up to thirty carbon atoms, which cannot be distilled; for example, wax esters may be separated from glycerides. *Cis* and *trans* isomers of some compounds have also been separated. The nickel complex, $Ni(CN)_2.NH_3.C_6H_6$, has been used to obtain benzene of 99·992 ± 0·004 per cent purity by a very simple operation.

Some inclusion structures do not give good separations. Thus, 'Dianin's compound' (4-*p*-hydroxyphenyl-2 : 2 : 4-trimethylchroman) includes a great variety of molecules; its cavities are very large and therefore not selective. Tri-*o*-thymotide, which also gives many inclusion compounds, forms enclosing structures held together by van der Waals forces only. In this case the cavities are adaptable to some extent to the included molecule. Although a particular tri-*o*-thymotide structure may occur only with included molecules the dimensions of which lie within certain limits, this does not prevent formation of adducts with other molecules with a different form of tri-*o*-thymotide enclosure. In such circumstances separations through addition compounds may be possible but are not likely to be efficient. There is, however, a form of separation for which tri-*o*-thymotide is very suitable. It normally crystallizes as a racemate, but in many of its adducts it is spontaneously resolved into a conglomerate of *dextro* or *lævo* crystals. The cavities in these crystals are, like the molecules, enantiomorphous, and may include preferentially either *dextro* or *lævo* molecules. Since tri-*o*-thymotide racemizes rapidly in solution, it is possible to remove only the one enantiomorphous form of crystal from a solution and to recover from it the included substance. In this way racemic secondary butyl bromide has been resolved, and the efficiency of the process approaches 100 per cent. Optical resolutions may also be carried out with urea adducts; the process depends on the left- or right-handed spiral arrangement of the enclosing urea molecules, but seems to require many repetitions. The cyclodextrins have also been used for optical separation.

The enclosing components described have been found largely by accident. Once such a structure is known, it is possible to foresee which molecules it is likely to accept or reject and thus to employ inclusion compounds for separation purposes. It is not so easy to predict which molecules will form enclosing structures. It is desirable to have cavities which can be modified to fit a particular encloseable molecule, and the observation of large cavities in some inclusion compounds suggests how this might be done. If a molecular arrangement analogous to that of β-quinol but with much larger cavities could be built up, it might be possible to vary the cage-forming component by the addition of a substituent without drastic change in the main structure.

A major problem in industrial and academic science is how to separate the multitudes of chemical species from one another, by neat, simple and effective methods, and new principles for doing this are constantly being sought. A novel method consists in using crystal lattices as molecular sieves, and this was discussed in the third, and last, paper, given by Prof. R. M. Barrer (Imperial College, London), his paper being entitled the "Separation of Molecular Mixtures using Crystal Sieves". A crystal with an open lattice is employed quite literally to sift molecules. Those molecules of the wrong shape or size are held back, while others of appropriate form pass easily into the crystal, which then occludes them copiously. The separations achieved are fully quantitative in a great many cases, by the single, clear-cut operation of exposing the crystal powder to the molecular mixture, or filtering the molecular mixture through a bed of the crystals. An account was given of some of the work done in Prof. Barrer's laboratory in introducing the molecular sieve method, and in characterizing, operating, modifying and synthesizing crystal sieves of various kinds.

Naturally occurring crystal sieves were discovered among the crystalline zeolites. In these species, which are all aluminosilicates, $SiO_4$ or $AlO_4$ tetrahedra are built into more complex structural units, often polyhedra. These polyhedra may have considerable cavities at their centres (chabazite), or it may be the stacking of the polyhedra which creates new and larger cavities (faujasite; natrolite, thomsonite, scolecite). Windows open into the cavities and provide ready means of entry or exit for sorbed molecules and means of transit from one cavity to another. These windows also determine the molecular sieve properties of the crystal as a whole. By sharing of oxygen atoms, the polyhedra are built into three-dimensional structures which often display remarkable rigidity and permanence, while being permeated by cavities interconnected by windows. The volume of the cavities may be more than 50 per cent of the volume of the crystal. Four major categories of crystal sieve were then characterized by Prof. Barrer, using certain molecules of known dimensions as yardsticks. A general order of openness of the crystal lattices in a few cases is: faujasite > calcium-rich chabazite > sodium-rich mordenite > calcium-rich mordenite or calcium-rich levynite > analcite.

Faujasite, when freed of its crystal water by heat and evacuation, freely occludes *iso*-paraffins and simple aromatics and naphthenes; chabazite will not occlude *iso*-paraffins, aromatics and naphthenes, but does occlude *n*-paraffins, and molecules of smaller cross-section; sodium mordenite will not occlude *n*-paraffins, from $C_3$ upwards, but sorbs $C_1$ and $C_2$ paraffins, argon atoms, and nitrogen, oxygen and similar small molecules; while calcium-mordenite or levynite does not sorb even $C_1$ and $C_2$ paraffins, and yet still occludes nitrogen, oxygen and similar small molecules. Typical quantitative separations, using the appropriate crystal sieve, have been made, *inter alia*, of aromatics, naphthenes or *iso*-paraffins from *n*-paraffins; of mono-substituted methanes and ethanes with amine, hydroxyl, chloride, bromide or cyanide as substituents from similar mono-substituted *n*-paraffins having the substituent group at a secondary carbon atom; of mono-substituted methanes from similar mono-substituted ethanes; or of simple inorganic species (water, ammonia) from organic species. Mixtures which are azeotropic, or in which the constituents have virtually the same boiling point, can readily be separated if appropriate size and shape differences arise between their molecules (for example, water–ethyl alcohol; or *n*-$C_7H_{16}$–*iso*-$C_8H_{18}$).

The crystal sieves have been modified, within limits set by a given aluminosilicate framework, by ion exchanges of the type: 2Na ⇌ Ca (change of valence), Na ⇌ K (change in radius of cation); and by more complex isomorphous replacements such as NaAl ⇌ Si. The sieve characteristics can also be changed by leaving small amounts of polar molecules (for example, water, ammonia, methylamine) in the crystal lattice. In these ways a great diversification of sieve types can be effected, and an almost continuous gradation of such sieves now appears possible. Finally, a substantial number of zeolites has been synthesized by hydrothermal growth from gels, representative of all main classes of sieve. Many of these zeolites have no natural counterparts, and raise interesting problems in crystal chemistry and crystal growth.

---

# INFLUENCE OF SPACE FLIGHT ON ENGINEERING AND SCIENCE*

By MILTON W. ROSEN

Naval Research Laboratory, Washington, D.C.

WITHIN the past few years many scientists have predicted seriously and confidently that human beings from the Earth would, in the foreseeable future, travel to the Moon and the nearer planets. The ranks of those who would dispute this prospect are diminishing rapidly. Although much of the progress is still guarded by military necessity, space flight is emerging as an activity in its own right—one that can command the efforts of many engineers and scientists.

In the United States the exploration of the upper atmosphere, the frontier to space, is being conducted vigorously. Pilots of rocket aircraft have experienced conditions approximating to those in free space, if only for a few minutes. The effect of space flight upon the human organism is being investigated—the U.S. Air Force maintains a Department of Space Medicine. There is an international organization devoted to the promotion of space travel, and there are space flight societies in twenty-three countries.

The ancients, except for a few rare individuals with greater insight, conceived of the world as an enclosure; they stood upon the Earth at the bottom and gazed upward at a blue ceiling upon which a multitude of lights, a few great and many small, seemed to move under the influence of an unseen hand. The atmosphere filled this enclosure, and it was believed that if man had wings he could fly to the ceiling and determine the source of the lights. If a few philosophers guessed more nearly at the truth, certainly the average man had no better conception of the universe than the fanciful picture just described. There could be no valid idea of space flight until Copernicus, Kepler and Galileo placed the Earth in its true relation to the universe and at the same time gave dimensions to space.

When at last the Moon and the planets were found to be material bodies not unlike our Earth, it was possible to ponder whether the immense separating distances could be traversed by man or any man-made device. The situation was made even more discouraging when, in 1686, Newton[1] defined the nature and the magnitude of gravitational attraction. If previously there had been some fanciful hope of visiting celestial bodies, now surely it appeared that man was destined to remain for ever a prisoner of his own planet. In view of the great distances, it seemed unlikely that the atmosphere could extend through interplanetary space, and any suspicion that it might was laid to rest when Torricelli's barometer was carried to a mountain-top and taken aloft by the early balloonists.

Although Newton brought man face-to-face with one formidable aspect of the problem, namely, gravity, he also provided, in his three laws of motion, the key that would unlock the door to space. The fundamental equation of rocket action in free space and hence of space flight:

$$V_b = C \ln \frac{M_0}{M_b}$$

where $V_b$ is velocity of rocket at the end of burning, $C$ is velocity of exhaust jet, $M_0$ is initial mass of rocket, and $M_b$ is mass of rocket at the end of burning, is derived by integrating Newton's third law of motion. Nevertheless, more than two centuries were to pass before anyone performed the integration or realized that the simplest embodiment of Newton's third law, a rocket, is the only machine capable of propelling itself in a vacuum.

---

* Substance of a paper read before Section G (Engineering) at the Bristol meeting of the British Association on September 1.

By the beginning of the twentieth century the physical sciences had advanced to the point where it was inevitable that someone would develop a valid theory of rocket action and would apply the theory to the problem of escape from the Earth. The task was accomplished by three men working independently in three different countries. The three had much in common—they were teachers, one at a small university, the other two in secondary schools. All three were motivated by the desire to explore interplanetary space and presented their findings with conviction, even though they were regarded by most of their contemporaries as prophetic dreamers. The men and their works are: Ziolkovsky, "The Exploration of Cosmic Space by Reaction Machines" (1903); Goddard, "A Method of Reaching Extreme Altitudes" (1919); Oberth, "The Rocket into Interplanetary Space" (1923). Any one of these three publications, had it been widely read and accepted, would have sufficed to lay the groundwork for space travel, because each man clearly understood and asserted the following fundamental concepts: (1) Escape from the Earth is possible by the application of a moderate acceleration over a substantial period of time—at least several minutes. (2) Such acceleration can be produced in a vacuum by a rocket. (3) The rocket must (*a*) have high thermal efficiency (that is, high velocity of the ejected matter), and (*b*) consist mainly of propellant material (that is, have a high ratio of fuel weight to total weight). (4) High thermal efficiency would be obtained most readily from the chemical combustion of liquid fuels.

Ziolkovsky[2] started by examining Jules Verne's cannon and also the balloon as a means of reaching very high altitudes. Both approaches died quickly under mathematical analysis. He proceeded next to the rocket and developed the fundamental equation previously noted. Realizing that energetic fuels were required, he determined from thermochemical calculations the heat release of various liquid combinations. When he computed the velocity that could be attained, in theory at least, he realized it was sufficient for escape from the Earth.

Goddard[3], alone of the three, proceeded from experiment to theory. Using smokeless powder in a heavy-walled steel combustion chamber, he produced a jet velocity of almost 8,000 ft. per sec., a seven-fold improvement over ordinary rockets and the highest velocity of matter attained up to that time outside electrical discharge tubes. Also, he proved by tests in a vacuum that a rocket does not produce its force by pushing on the air behind it—a fact that he knew from basic physics, but felt had to be demonstrated. He observed correctly that the jet velocity was greater in a vacuum, but he attributed it erroneously to more efficient ignition. Although Goddard did not turn to liquid fuels until after his basic paper was published, he achieved the first flight of a liquid-fuel rocket, an event that took place on March 16, 1926. Goddard[4] continued his experiments for more than two decades, during which time he developed, in rudimentary form, almost every component of modern rocketry. Not one of his components would be considered reliable by present-day standards; realizing the prodigious task he had set out to accomplish, he would repeatedly add a new component before perfecting the previous one. In retrospect, it appears that Goddard was attempting, single-handed, to encompass the entire field of liquid-fuel rocket development, a task that would eventually tax the abilities of thousands of engineers and scientists.

Oberth[5], in his treatise, gave the most complete theoretical analysis and carried it farther into the realm of space travel than either of the others. He stated at the outset the four propositions he would attempt to prove: (1) considering the present state of science and technology, it is possible to build machines that could rise beyond the atmosphere; (2) after further development these machines will be able to attain such velocities that, left undisturbed in the depths of outer space, they will not fall back to the Earth and will even be able to leave the zone of terrestrial attraction; (3) these machines could be constructed so as to transport human beings, probably without damage to their health; (4) under certain economic conditions the construction of such machines might be profitable.

Oberth began by developing the theory of the liquid-fuel rocket and describing its construction. He proceeded to discuss applications of the rocket, first as a high-altitude sounding vehicle, then as an Earth satellite, and finally as a space-ship for interplanetary travel. He developed the concept of synergic (minimum energy) ascent trajectories. Without doubt, almost every later book on space flight owes much to Oberth's encompassing study.

Whereas the first quarter of this century provided the theoretical background for space flight, the second twenty-five years may be viewed as the period of experimental preparation. It saw the liquid-fuel rocket develop as a practical engine for the propulsion of aircraft and guided missiles. Many fuels and oxidizers were explored—a few saw widespread use. An assortment of auxiliary apparatus—pumps, turbines, valves and regulators—was developed to feed and control the rocket motor. The steering of a large rocket vehicle was mastered by means of gyroscopes and jet controls. Great progress was made in the aerodynamics of supersonic flight, in structural design and in the use of high-temperature materials.

Of the early experimenters, three groups were most noteworthy. The work of Goddard as an individual has been referred to previously. In Germany, the Verein für Raumschiffahrt, fired by Oberth's monumental work, undertook to develop a small workable rocket called, appropriately, 'minimum-rakete' ('Mirak' for short)[6]. In the course of several years they made hundreds of static firings and numerous brief flights. The American Interplanetary Society drew its inspiration largely from abroad, so secretive was Goddard about his experiments. Indeed, when in May 1933 the Society finally achieved a first liquid-fuel rocket flight, they were unaware that Goddard had progressed far beyond his first flight seven years before.

The *V2*, the development of which started in the middle of this period, was the largest single engineering advance in the field of rocketry. By applying thousands of engineers and scientists in a concerted effort, the German Government was able in six years to transform the liquid-fuel rocket from a small, sputtering vehicle, capable of ascending a few hundred feet, into a giant projectile with a range of 200 miles and a velocity of one mile per second. The *V2* was a material embodiment of Oberth's ideas and, although he conceived the liquid-fuel rocket as a vehicle for space travel, he also foresaw its possible use as a bombardment weapon. Actually, he hoped that the rocket missile would be a deterrent to, rather than a tool of, war.

After the War, the major activity leading to space flight took place in the United States in the form of upper-air research with instruments carried in rockets. In a programme which is still continuing, scientists from government laboratories and universities explored the upper atmosphere using at first captured *V2* rockets and later, as they became available, 'Aerobees' and 'Vikings', both of which were designed specifically for probing the atmosphere in the region between 50 and 150 miles above the earth. In this way, knowledge of the pressure, temperature, density and ionic content of the atmosphere has been extended up to 135 miles by direct measurements. The solar spectrum has been recorded in the far ultra-violet. X-rays have been detected in solar radiation and their role in the formation of the ionosphere has been postulated. The number and the mass distribution of primary cosmic rays have been recorded in emulsions carried aloft in rockets. Small animals (monkeys and mice) were sent aloft, and their physiological reactions observed during a period of weightlessness. For nine years man has been exploring the frontier of space as a prelude to flight beyond the atmosphere.

It is always tempting to draw parallels, and it might appear, at first glance, that the advance toward space flight parallels the progress of aviation, with the latter preceding in time. The same elements of progress are evident in both fields, but one cannot fail to note the differences and contrasts. Although much theoretical work had been done on fluid mechanics and experiments performed in wind tunnels and with gliders, there was at the time of the first mechanical flight no adequate theory to explain the lift of a winged vehicle[7]. We knew that the Wright Brothers' aeroplane flew; but we could not explain why or how it flew. By contrast, the motion of a rocket, as we have seen before, was well understood before Goddard's first attempted flight. This is no paradox—it is apparent that the mathematical treatment of flight within the atmosphere is much more difficult than the analysis of flight in free space.

In both fields there was a period when development was nourished mainly by amateurs; in aviation it was the first decade of this century, for rocketry the late 'twenties and early 'thirties. In both cases the advance was given great impetus by a war; the First World War for aviation, the Second for rocketry. But I doubt if there is in the history of aviation any single step forward comparable in magnitude to the creation of the *V2*. Aviation has been characterized by gradual, steady development, fostered to a large extent by its economic returns as well as its military advantages. There have been several significant milestones; one of the most noteworthy was the development by Whittle and others of the turbojet engine, which in the short space of a dozen years has completely displaced the piston-driven propeller in high-speed military aircraft and may soon dominate the field of commercial aviation.

In pursuing this rather loose parallelism I have tried to estimate what period in the history of aviation corresponds to the present status of space flight. It seems to me that we are now at a point roughly corresponding to the period before Lindbergh's historic flight across the Atlantic. The significant event we are awaiting is the first orbital flight of a manned earth satellite[8]. In both cases, at the time being considered, the vehicle had been developed to a reasonable degree of reliability and many flights of shorter range and duration had been made. But again, there is a significant difference. Aviation has always implied manned flight; in rocketry most of the progress thus far has been made in unmanned, automatically controlled vehicles. Our technology has advanced to the point where we need not risk human life in experimental rocket flights; on the road to space, instruments will always go first and will point the way for men to follow.

Prior to establishing the first manned satellite, two important techniques will have to be mastered. First, there will be a period of experimentation with unmanned, instrumented satellites during which time problems of propulsion, staging and navigational control will be worked out. The environmental hazards—cosmic radiation, meteors, solar heat (and the absence of it), and possibly weightlessness—can be evaluated. World-wide realization that this first problem is being attacked vigorously came when, on July 29, 1955, President Eisenhower announced that the United States would launch small instrumented satellites during the International Geophysical Year (1957–58). By their statements in support of the President's announcement, many noted scientists attested to the feasibility and usefulness of the instrumented satellite. It is significant, also, that the United States invited international co-operation and offered to make its scientific findings available to all nations.

The second problem is the one of safe return to the Earth's surface. The relative speed of roughly five miles per second between the orbiting vehicle and the earth's surface must be brought to zero. Obviously, this will be done by allowing the satellite to transfer its energy to the atmosphere. But this process must be controlled with great precision, lest the satellite absorb too much of the energy in the form of heat. Much will be learned by observing the return of instrumented satellites; but the final preparatory steps will probably involve manned flights at gradually increasing re-entry speeds.

I have placed Lindbergh's flight and the first manned satellite in juxtaposition because one has, and the other will, I believe, so excite the world's imagination that future progress will be greatly accelerated. One cannot say when the desired event will take place—much hard work remains to be done—but it is not uncommon for scientific achievements to precede their predicted arrival. The mechanical components—engines of sufficient power and controls of requisite precision—are within sight. If it is argued that the human hazards are great and, at present, poorly understood, let it be remembered that the first orbital flight need only be brief—a matter of several hours. In this respect the ordeal may be less prolonged than Lindbergh's flight, but certainly no less demanding upon the pilot's judgment and courage.

We have seen that although space flight is yet to be achieved, its prospect has had, in the past fifty years, an appreciable influence upon science. The greater influence by far lies in the future. The advances in our technology necessary to achieve manned flight in space and those required to exploit it can be readily delineated. But a more important result will, I believe, be the impact of space flight upon scientific thought and education.

In the United States to-day we are faced with a serious shortage of engineers and scientists even though the demand is great and the remuneration is ample. Almost every prospective technical graduate of American universities is showered with offers of employment, and our newspapers and magazines are filled with advertisements for men with technical training. The most appalling aspect of this situation is that it is likely to continue for many years. A recent survey shows that the study of physics in American public high schools has been declining for more than half a century. Whereas in 1895 more than 95 per cent of high-school graduates had taken a course in physics, by 1952 only 21 per cent of graduates had ever studied it[8]. For many years the increase in high-school enrolment more than offset the decrease of specialization in physics, but now the waning interest is taking its toll. To-day only about half the public schools offer a course in physics, and a quarter of these have no laboratory facilities. There is a critical shortage of science teachers, due in part to the attractions of industry, but more to the lower status and wages accorded the teaching profession. But these factors can be remedied with sufficient effort—a deeper and more serious cause is the lack of interest on the part of our youth. Why do they turn away from a career in science ? We can only grope for the answer. Perhaps they sense, better than their elders, that too much of our scientific talent is engaged in the unproductive task of developing weapons for war. Is there much inspiration to devote one's life to this end, especially when we are rapidly approaching the borderline of total destruction ?

I believe that space flight might serve in no small measure to turn men's minds toward a more appealing scientific goal. As the exploits of Cabot, Drake and Davis inspired many generations of Englishmen to turn to the sea, so may the first astronauts reawaken our youth to the romance of scientific exploration.

# UNITED KINGDOM ATOMIC ENERGY AUTHORITY

## ANNUAL REPORT

THE first annual report of the United Kingdom Atomic Energy Authority* covers the period from July 19, 1954, when the Authority came into being, to March 31, 1955. In that period the Government has published the Programme for Nuclear Power and the Defence White Paper announcing the decision to proceed with the development and production of thermonuclear bombs. Further information has also been given in a brochure, "Britain's Atomic Factories", and in the booklet, "The Commonwealth and Nuclear Development", issued by the Central Office of Information last June ; and the technical information made available at the International Conference on the Peaceful Uses of Atomic Energy at Geneva in August has also robbed the report of some of its technical interest. Nevertheless, the report reveals an impressive picture of the continued growth of a project which has been expanding since its inception in 1945, and of the wide range of research on which that expansion is based.

The latter aspect, and the scarcity of skilled man-power, which constitutes the chief threat to the fulfilment of the programmes in accordance with the time-table to which they are closely geared, are discussed elsewhere (see p. 1183) ; but the shortage of technological skill is put in the forefront of the report, as the development of atomic energy is unique in the variety of specialized skills which it demands. After recapitulating briefly the steps that led to the establishment of the Authority, which at present consists of the chairman, Sir Edwin Plowden, and four full-time and three part-time members, the report merely records the net estimates of expenditure for 1954–55 at £53,675,000 and £50,562,000 respectively ; the actual expenditure will be presented to Parliament and published. No figures for staff are included ; but the senior staff are listed in an appendix. As to patent policy, it is stated that the programme for nuclear power will extend to industry and to the electricity authorities the use of atomic energy inventions, some of which also have general applications in the chemical, metallurgical and instrument fields. Where inventions are not secret, the Authority's policy is to grant non-exclusive licences to suitable United Kingdom recipients unless, exceptionally, the invention can be more appropriately exploited by the National Research Development Corporation.

Apart from a brief reference to the weapons programme, the technical aspects of the Authority's work are discussed in a series of chapters dealing successively with the materials, the reactors, the nuclear power programme, the isotope programme and with progress in research. There is a further chapter on health, waste disposal and safety. In regard to materials, the Authority does not normally prospect for new uranium deposits on its own account, and its main contribution to the provision of uranium has been through the encouragement given to producers by the assured market offered by the Colonial Development Agency contracts, from which British atomic energy work has so far drawn all its supplies. As part of its procurement programme it has provided the considerable capital sums necessary to develop and exploit deposits. On arrival in Britain, the uranium ore or concentrate is processed at the Springfields factory of the Industrial Group. The initiation of the nuclear power programme will involve a great increase in the amount of uranium processed, and the creation of capacity for this higher throughput will be used as an opportunity to improve the whole process. A low-separation diffusion plant has been built at Capenhurst in addition to the main plant, and in this the uranium which has been depleted in its content of fissile material can be restored to its original composition by carrying out a partial separation from the uranium-238 atoms, thus permitting much greater economy in the use of uranium, since the restored material can be put through the pile again and used to produce more plutonium. This low-separation plant has worked satisfactorily throughout the period, as has the primary separation plant at Windscale, where the piles have worked efficiently and produced the planned amount of plutonium. Research is being carried out to increase our knowledge of thorium and of the production of uranium-233. A new distillation-column packing of such high capacity that the capital cost could be brought down to nearly half that of a conventional 'bubble-cap' type of packing has been developed for the separation of 'light' and 'heavy' water, and this packing, 'Spraypak', is potentially useful in the general field of distillation.

---

* United Kingdom Atomic Energy Authority. First Annual Report for the period 19th July, 1954–31st March, 1955. Pp. vii+35. (London : H.M. Stationery Office, 1955.) 2s. net.

In addition to describing the various reactors under construction, the report outlines some of the research in this field proceeding at Harwell, notably the detailed design study of light-water reactors known as LEO (Low Enrichment Ordinary Water). The Authority expects that by 1957 it will be supplying electricity from Calder Hall to the Central Electricity Authority. Much of what is said in the report as to the programme for nuclear power and the isotope programme is already well known. For the year ended March 31, 1955, the output of isotope consignments totalled 18,835, an increase of 16 per cent, and the value of radioactive products sold was about £450,000, of which 35·6 per cent was exported to some forty countries. There was a marked increase in the use of small amounts of separated fission products for industrial and medical purposes, and the accessibility of many of the commoner compounds of such isotopes as phosphorus-32, iodine-131 and sulphur-35 has been increased by improvements in technique. There is evidence of a growing interest within industry generally in the radioactive tracer technique.

In regard to research generally, facilities available for determining the exact nature of the interactions of neutrons of different speeds with various elements are being extended by developing a novel and much more powerful source of neutrons, and the Authority is also fostering a programme of fundamental research on the unresolved problem of the forces which bind together the elementary particles in atomic nuclei. Studies in the field of radiation chemistry have shown that important chemical and structural changes can be effected in materials irradiated by powerful radioactive sources. Among these are improvements in the heat resistance and other physical properties of plastics and in the properties of lubricating oils. To provide further facilities for this work and to assist industry with advice and tests, a Technological Irradiation Group was established as part of the Isotopes Division of the Atomic Energy Research Establishment in April 1955. A new instrument of value outside its original application is an infra-red spectrometer developed to record continuously the percentage of heavy water in a mixture with ordinary water, while the Research and Development Branch of the Industrial Group has dealt successfully with the development of new solvent processes for the extraction of uranium from its ores and with the application of the 'fluidized bed' technique to processes used by the Group. Metallurgical research on the extraction of uranium, plutonium, thorium, zirconium and beryllium from their ores and on the working of the metals is yielding techniques of increasing application in the manufacture of reactor fuels and the special canning materials which contain them, and much effort is directed to the search for corrosion-resistant alloys and to the modification of the metallurgical structure of reactor fuels or their design so as to control undesirable effects. An electronic analogue computer is being developed to simulate the operation of a large atomic power station by showing directly, and so without the need for elaborate calculation, how the essential factors involved change with time and interact with one another.

Much work has been done on the disposal of radio-active wastes, several methods having been developed which enable this to be dealt with safely, and the report describes the storage and deep-sea disposal methods used for solid wastes. Sea disposal is carried out in the Atlantic beyond the continental shelf. For effluent disposal considerable research and field-tests have established rates of discharge which can in no way affect either the health of the public or the fisheries or seaweed industry. In regard to gaseous effluent, it is pointed out that the prevention of interference with the technical work of the Authority often demands an even more stringent control of discharged activity than is legally demanded for public health or other reasons.

# SCIENTIFIC FILM ARCHIVES

By DR. A. R. MICHAELIS

PAST and present knowledge can only serve the future if permanently preserved and patiently perpetuated. If this knowledge is recorded in writing, and preserved as a book in a library, then with little trouble, small expense, and by the use of microfilm, practically every word that has ever been printed can to-day be read by anyone in the world. How infinitely worse is the situation if knowledge has been gained by, or recorded on, motion picture film; that many scientists have done so and used cinematography in their biological, anthropological, psychological and medical work was recently shown in a survey on research films[1]. Unfortunately, only a very limited number of these films have found their way into archives and are available for reference to other research workers, anxious to consult them. In the past, one reason for this dearth of scientific film archives has been the difficulty and cost of storing nitrate film; the problems involved and their expensive solutions have been fully and authoritatively discussed by Brown[2] in a recent paper. Since about 1950, however, the universal use of cellulose triacetate safety film base for both 35-mm. and 16-mm. motion pictures has at least removed one of the difficulties hindering the establishment and growth of film archives. It is expected that this type of film base, when stored in conditions similar to those for books in libraries, will last several centuries.

Film archives, devoted to the art of the film, have been in existence for many years, the oldest three and most important being the National Film Archive of the British Film Institute, the Cinémathèque Française in Paris and the Museum of Modern Art in New York. Since the Second World War, many other countries in Europe and overseas have started their own national collections of films; but the British National Film Archive is the only one in the world in which scientific films for permanent preservation have been systematically collected since 1949. The work of selection has been in the hands of the Science Selection Sub-Committee of the British Film Institute; in October 1955 it held its fiftieth meeting, exactly six years after its first gathering. During that time several thousand scientific films have been considered in detail, and about half of these were recommended for inclusion in the archives; owing to the difficulties, however, of obtaining copies and original prints of some of those recommended, not more than about one thousand have so far been actually deposited in the vaults. Scientific films which have been preserved are, of course, available to research workers for study; a request to view them should be addressed to: The Curator, National Film Archive, 164 Shaftesbury Avenue, London, W.C.2.

The first task which the selection committee faced was the adoption of basic principles to guide its decisions. It was agreed that a scientific film should be preserved if the subject-matter was of sufficient interest for the future, and secondly, if the film was an example of the use of a cinematographic technique during the course of a research project—in fact, a research film. The committee has rejected films the contents of which could be preserved better or more cheaply by photographs or by written descriptions. In the main, only British films have been recommended for preservation; but those foreign scientific films which were available in Britain, or which had a marked influence on British scientific thought, have not been excluded. Preference has always been given to actual records of scientific events, and reconstructions have only been accepted when originals were unavailable. Concerning subject-matter, priority has been given to films showing outstanding scientists at work, original experiments, dying native cultures and scientific heterodoxy. The only general rule, however, that was applied in doubtful cases and which was found workable was the question: "Is there any conceivable reason of subject or technique, why this film would be of interest to students of science in fifty or hundred years time, and why its loss might then be deeply regretted?".

Having established its terms of reference, the Committee was confronted in 1949 with an enormous number of scientific films from which to select. The only possible way of proceeding was the division of the whole field of science into its individual disciplines and in each case to call for lists of scientific films. Several lists of this kind were then in existence, and many others were later prepared, either by subject experts, or by committees of the Scientific Film Association, which has in so many ways furthered the work of the Science Selection Sub-Committee. Among the many subjects which the committee considered were, for example, astronomy, chemistry, mathematics, psychology, town planning, veterinary science, medicine, economics, biology, aeronautical engineering, forestry, horticulture and agriculture. In each case, subject experts were asked for their views on particular films; they then reported back to the committee, often only after spending many hours in viewing the original material. Scientific film experts have also given freely of their time to help the committee in its important work of selection, and all who could have served on the committee itself for varying periods. Through its first fifty meetings, the committee has systematically surveyed a very large proportion of past scientific films, and its present task is to select films worthy of preservation from current productions, to discover forgotten research films, and to fill the many gaps that remain.

The committee has received great help from outside bodies, which have generously handed over their own collections of scientific films to ensure their permanent preservation; so, for example, a splendid collection of early aeronautical films was given by the Royal Aeronautical Society, and a similar gift was received from the archives of the Physiological Society. The committee earnestly hopes that other learned societies which have historical film material will follow these examples, as only scientifically controlled archives can fulfil all the rigorous conditions required for the permanent preservation of early scientific films, many of which were recorded on unstable nitrate film. Producers of scientific films have been no less generous, and at present the National Film Archive receives automatically one print of each film made by the Shell Film Unit; the National Coal Board, Guy's Hospital, Imperial Chemical Industries and the Anglo-Iranian Oil Company have also given many of their films. Again the committee hopes that others will present their productions as well, so that complete series will be available for study in a hundred years time.

A very great deal of work remains to be done. At present there is an almost complete lack of biographical film material of eminent scientists, and it might here be suggested that with the award of a Nobel Prize, or the Copley Medal, a short record film of the recipient is prepared. Such a film and its accompanying sound-track would show better than photographs or written descriptions the personality of the prize-winner; it should, of course, give full details of the particular research technique which brought him distinction. Many research films, at present lying forgotten in desks and files of their producers, need to be rescued for preservation, and the committee would gladly accept them. It can assure the donor that he would not lose his copyright and that duplicates will not be made unless his express permission is given. The committee sincerely hopes that other nations will follow its own example and that either national film archives abroad, other scientific film associations, or scientists in overseas countries will form their own scientific film archives to preserve and to perpetuate scientific data for future research. Johnson[3], who also pleaded for such archives in the United States, concluded a paper on this subject: "It is hoped that those who truly wish to serve Science, even though they do not believe that motion pictures will achieve a place of major importance in scientific institutions, will accord posterity the opportunity of deciding the matter by creating libraries or reservoirs of motion picture films".

# THE WENNERGREN INTERNATIONAL CENTRE FOR SCIENTIFIC RESEARCH

THE Swedish industrialist Dr. Axel Wenner-Gren has recently announced a new donation for the benefit of science, to be administered by a new foundation called the WennerGren Centre for Scientific Research. Some of his earlier gifts for science are well known. In 1937 he founded the WennerGren Society in Stockholm and the Institute for Experimental Biology in the University of Stockholm. The Society has supported the Institute as well as many research activities in other fields. In 1941 he created in New York the Foundation for Anthropological Research, which has among other activities not less than five scientific expeditions in South and Central Africa studying the first traces of the early history of man. This Foundation also serves most successfully as a clearing centre for a large number of universities and specialists in the field of social and anthropological sciences. It may be mentioned that the discovery of the carbon-14 method for age-determination by Prof. W. F. Libby was the product of an investigation supported by this Foundation.

Dr. WennerGren's new donation may be considered as a first step for stimulating and supporting international co-operation in scientific research on a broader base. The members of the board of the new Foundation have just been announced. Chairman of this Foundation will be the Lord Chamberlain of Sweden, Birger Ekeberg, who is also chairman of the WennerGren Society and of the Nobel Foundation.

The first undertaking of the new Foundation will be a building to serve as the permanent seat for the central organization. The building also will have—and this is a very important point—accommodation for housing (at moderate costs) foreign scientists who are doing research work at one of the many research institutes in the Stockholm area. For this purpose, there will be furnished apartments and rooms for about a hundred scientists, restaurants, club-rooms, lecture halls, etc. It will also serve as a meeting centre for national and international symposia, as well as for smaller and informal gatherings for the promotion of personal contacts between scientists from different research fields.

It is expected that the Government of Sweden and the City Council of Stockholm, which have shown an active interest in the plans, will provide a suitable, centrally located site for the building. According to the present plans, the new building will be ready for occupation in about two years.

From the communication in which Dr. Wenner-Gren announced his new donation, the following words may be cited: "For a long time I have personally been convinced that many of the great problems of mankind can have a satisfactory solution only on a scientific basis. That is the reason why I have tried to support both pure and applied research for many years and I have now decided to make available—one could say by instalments—my resources for the furthering of such activities".

# OBITUARIES

## Dr. W. G. Shilling

DR. W. G. SHILLING, head of the Materials Division of the Aeronautical Inspection Directorate, Ministry of Supply, died suddenly on October 16.

William George Shilling was born at Faversham, Kent, on February 21, 1899. During 1910–16 he attended the Henry Wreight School, now the Faversham Grammar School, where he passed the Inter.-B.Sc. (London) Examination. He joined the Army at the age of seventeen, was commissioned and was awarded the Military Cross in 1918. His rank on demobilization in 1919 was staff major.

Shilling spent the next eight years at East London (now Queen Mary) College, University of London. He graduated B.Sc. (honours in chemistry) in 1921 and then began research on the specific heat of gases under the direction of Prof. J. R. Partington. After making very accurate determinations at ordinary temperatures, he extended the method, which involved measuring the velocity of sound, to higher temperatures up to 1,800° C. Shilling was a most ingenious and skilful manipulator, expert in devising and perfecting apparatus. He also collaborated with Prof. Partington in writing a book, "The Specific Heat of Gases", a classic in this field. Shilling was awarded the M.Sc. in 1922 and D.Sc. in 1927.

During 1927–43 Shilling was in charge of chemical and physical research for the International Paint and Compositions Co., Ltd., Newcastle upon Tyne. His main work was on ships' under-water paints, but he also dealt with all other types of protective and decorative finishes. During this time he played a leading part in the local civil defence organization.

In 1943 Shilling joined the Aeronautical Inspection Directorate as the assistant director in charge of the non-metallic materials branch, becoming head of the Materials Division in 1947. For some years he was also responsible for the technical direction of the A.I.D. Laboratories at Harefield, being especially concerned with the development of new methods of inspecting and testing the wide range of materials and equipment used in Service aircraft and ground installations.

Throughout his life, Shilling retained his manual dexterity, and he was interested in clock making and the construction of electronic apparatus. He kept his love of the countryside and was never happier than when working on his estate; he was a loyal member of his Church and a keen Mason. His modesty, good nature and integrity won Shilling a host of friends in many walks of life, who mourn his untimely death. He is survived by his widow and two daughters, whose consolation will remain that his happy home was the centre of his life.

H. J. CURNOW

### Dr. J. W. Nicholson, F.R.S.

May I supplement Prof. W. Wilson's account of Dr. J. W. Nicholson in *Nature* of December 3 with a reminder that throughout most of his working life Nicholson was prominent on the British Association Mathematical Tables Committee, of which he was secretary from 1910 until 1920 and then chairman until his retirement ? It is to be regretted that his name is nowhere conspicuous in the volumes issued by the Committee after 1930, for it was under his influence that a number of people, each with a pet function or a pet range of his own, became a body concerned collectively with the principles and problems of computation and presentation. The decade in which the Committee regained and enhanced the prestige which it had enjoyed in the nineteenth century was preceded by a decade of exploration, discussion, and anxious self-criticism ; and it was owing to Nicholson's mathematical versatility and uncanny power of focusing attention on the essential points on both sides of any argument that a decade as unspectacular as a wheatfield in spring was also as rich in vitality and in promise destined to be fulfilled.

# NEWS and VIEWS

## Chemistry at the Royal Holloway College, London: Dr. E. J. Bourne

Dr. E. J. Bourne, reader in organic chemistry in the University of Birmingham, has been appointed to the chair of chemistry at the Royal Holloway College, University of London, in succession to the late Prof. G. Williams. Dr. Bourne, who is thirty-three years old, received his early education at Rugeley Grammar School and entered the University of Birmingham in 1939. He graduated with first-class honours in 1942, gaining the Frankland Medal and Prize and a University research scholarship. He was awarded his Ph.D. in 1945 and his D.Sc. in 1953. He has published some eighty papers and has gained an international reputation for his work on carbohydrates, particularly in the field of starch chemistry. His most notable early work, carried out in close association with the late Sir Norman Haworth and Prof. S. Peat, was on the isolation and characterization of the well-known 'Q' enzyme which synthesizes the amylopectin component of starch. He has made outstanding contributions to the enzymic synthesis and degradation of starch and other polysaccharides such as nigeran and dextran. His more recent work, largely carried out in collaboration with Prof. M. Stacey and numerous pupils, has been concerned with the chromatography and infra-red examination of sugars, application of carbon-14 in carbohydrate synthesis and the biological synthesis of oligosaccharides. With Dr. J. C. Tatlow he has made notable contributions to the reactions of trifluoroacetic acid. At present he is interested in the effects of $\gamma$-radiation on organic reactions and on some theoretical considerations regarding the formation of acetals. At Birmingham he has had wide experience in lecturing and in the organization of various laboratory courses, including extra-mural classes. He has served on the Faculty Boards of Biological Science and of Pure Science. He has been a particularly active member of the Midland Chemists Committee and has served as a local secretary for the meetings of the British Association and the Society of Chemical Industry and at present is a member of council of the Chemical Society.

## Physics in the University of Hull : Prof. G. F. J. Garlick

Dr. G. F. J. Garlick, lecturer in physics in the University of Birmingham, has been appointed to the chair of physics in the University of Hull, which has been vacant since the retirement of Prof. L. S. Palmer in 1954. Dr. Garlick was educated at Wednesbury Boys' High School and in the University of Birmingham. After graduation, he remained at Birmingham to take part in war-time studies of luminescent materials under the leadership of J. T. Randall, who as a Royal Society Research Fellow had already established a laboratory for the study of luminescence within the Department of Physics. During this period, Dr. Garlick gained not only enthusiasm for a branch of physics that was in rapid development, but also knowledge of the physical and chemical techniques upon which its further progress must be based. When Randall was appointed to the chair of physics at St. Andrews, Garlick was the only member of his group to remain in Birmingham and to continue this work, which for some years after the War was supported by the Department of Scientific and Industrial Research. He re-established a small but active group, whose interests were soon extended from polycrystalline materials bombarded with electrons or ultra-violet light to a wider field including the use of $\alpha$-particles and particularly of single crystals, in the growth of which he and his colleagues became highly expert. Latterly, studies have been made of phosphors emitting in the infra-red and of photoconductivity due to infra-red radiation. Dr. Garlick was appointed in 1949 to a University lectureship in Birmingham and has sustained a full share of teaching with no perceptible slackening in the flow of research publications. He is the author of a well-known monograph on luminescent materials and of several review articles.

## Environmental Control in Crop Experimental Work

Dr. J. P. Hudson, of the Department of Horticulture, University of Nottingham, has completed the first draft of a directory of equipment at present in use in universities and research stations in Great Britain for providing control of experimental environments. It is hoped eventually to publish it, under the title "Environmental Control Equipment in Britain", as Miscellaneous Publication No. 8 of the Department. Dr. Hudson is anxious that the directory should be as complete and accurate as possible, and will be pleased to send copies of the draft to any interested individuals or organizations who have not already been referred to, and to incorporate details of their installations in the final publication. The preliminary draft gives an account of the principles of environmental control, and of the different methods used to achieve it, as well as the list of existing installations. The use of controlled-environment equipment is rapidly spreading, and this directory should greatly assist anyone planning a new installation, by making it easy to draw on the experience of users of similar equipment.

## A 'Tropical Storm' photographed from a Rocket

In the June number of the *Monthly Weather Review*, L. F. Hubert and O. Berg, of the United States Weather Bureau and the United States Naval Research Laboratory, respectively, show and describe the first photographs taken from a rocket of the clouds of a tropical storm. The ascent was made in New Mexico on October 5, 1954, and was not made especially for photography of clouds from above. The photographs were taken by two cameras, one giving black-and-white and the other colour photographs, when the rocket was at a height of a hundred miles. The rocket rolled slowly as it moved so that the cameras scanned successive overlapping strips of the Earth. A composite photograph of the clouds over an area of 1,250,000 sq. miles is given in the article. The principal feature is a tropical storm centred near Del Rio, Texas, and the spiral structure of the clouds of the storm is clearly visible. This storm moved inland from the Gulf of Mexico and was quite a mild one, giving winds of only 18 knots over Texas. The convection was strong enough, however, to give three inches of rain at Brownsville, Texas, in three-quarters of an hour and more than six inches in three hours. The rocket photographs show two minor vortices the existence of which had not been suspected from the synoptic observations. From the photographs and other evidence, it is found that the axis of the storm extended about seven miles vertically and fifty-five miles horizontally. The slope of the axis fits well with a formula due to Panofsky giving it in terms of the curvature of the horizontal pressure profile and the horizontal gradient of temperature. The authors state that plans are in hand to fire rockets specifically for research into hurricanes and look forward to photography by rocket of the clouds over widespread tropical regions, such as South Equatorial America, which are as yet but little investigated.

## Higher Education in the Colonies

In a written reply in the House of Commons on December 6, the Secretary of State for the Colonies, the Right Hon. A. Lennox-Boyd, said that the Government had contributed £6,453,301 from 1945 to March 31, 1955, towards the capital cost of universities, university colleges and colleges of art, science and technology in the Colonial Territories. This total included £1,710,804 to University College, Ibadan, £1,087,223 to Makerere College, and £2,423,129 to the University College of the West Indies; but not the allocations of £1,019,000 and £350,000 to the University of Malaya and the Kumasi College of Technology, respectively, on which no call had yet been made. Although grants towards recurrent costs are not normally made, during the period 1954–55 grants for this purpose of £29,775 and £24,000, respectively, had been made to the University College of the West Indies and to Fourah Bay College, Sierra Leone. The total expenditure on education for the current year for the West Indies, Gold Coast, Nigeria, East and Central Africa, Malaya and Singapore was estimated at £56,666,967.

## The Tensor Club of Great Britain

During the past two decades the matrix and tensor calculus has found increasing application in the analysis of practical and particular problems in engineering, especially electrical engineering. About five years ago the Tensor Club of Great Britain was formed for the purpose of bringing together engineers and others interested in matrix and tensor analysis, and for spreading information regarding applications. The Club produces the *Matrix and Tensor Quarterly*, a magazine with about a hundred and sixty pages per volume which is sent out to about a hundred and fifty subscribers. Of the present members of the Club, about a half reside in Great Britain and about a quarter in the United States. There are also members in other countries, including France, Japan and India, and liaison has been established with the Tensor Society of Japan. The Club maintains a small lending library, and reciprocal arrangements exist for the exchange of magazines with the Mathematisch Centrum of Amsterdam, and with two universities in Japan. The membership of the Club is comprised mostly of engineers, physicists, mathematicians and chemists, employed in industry, research establishments, public utility companies and teaching. Information regarding membership can be obtained from S. Austen Stigant, 7 Courtlands Avenue, Hayes, Kent.

## Chemical Composition of the Larger Seaweeds

An account has been given by D. J. Wort (*Canad. J. Bot.*, 33, 4, 323; 1955) of the seasonal variations in the chemical composition of *Macrocystis integrefolia* and *Nereocystis luetkeana* growing in the coastal waters of British Columbia. These two seaweeds were collected at two stations at monthly intervals from October 1949 until September 1951. Analyses of fronds and of stipes were made for dry weight, ash, total nitrogen, total phosphorus, sulphur, copper, zinc, iron, ether-solubles, algin, mannitol, fucoidin, and laminarin. Generally speaking, the fronds had a higher content of all substances measured than did the stipes, and the content of the two species of algae showed parallel variation but differed in values. Dry weight and ash were at maxima in autumn and winter and at minima in April and May. During March, total nitrogen, ether-solubles, mannitol, fucoidin and laminarin were at their highest concentration. The plants in July contained the minima of total nitrogen, phosphorus and ether-solubles. The maximum for phosphorus occurred in December, and during this same month fucoidin was at minimum. The variation of sulphur, copper, zinc, iron and algin was such that well-marked minima and maxima were not evident. The author points out that while photosynthetic processes in the brown algae are considerably less well understood than they are in green plants, it is probable that phosphorylated mannose compounds are involved in the sequence, mannitol, a hexahydric alcohol, being important. The fronds of the two algae investigated have their highest mannitol contents during spring and early summer, the period of most active photosynthesis. The seasonal relationships of the other products of photosynthesis are also discussed.

## Banana Wilt Disease

In recent investigations, in Jamaica, of Panama disease or vascular wilt disease of bananas (*Fusarium oxysporum f. cubense*), J. Rishbeth has confirmed earlier findings on the mode and progress of infection and has contributed some new and interesting information on this important disease and on the biology of its causal organism (*Ann. Bot.*, N.S., 19, No. 75, 293; 1955). The pathogen has proved difficult to isolate from soil by plating, but it can be detected in soil by using a suitable host. Thus when small bananas were grown in pots under appropriate conditions, pathogenic isolates of *F. oxysporum* produced rhizome infections, whereas other isolates did not. When *F. oxysporum* isolates were obtained by plating from various sources, the proportions which proved to be pathogenic were: 91 per cent from the rhizome or pseudostem of plants showing typical wilt; 29 per cent from variously affected roots; and 0 per cent from soil. The information now available suggests that the banana pathogen, like other parasitic forms of *F. oxysporum*, has a limited host range; however, it has now been shown to cause a limited root infection of *Heliconia psittacorum* and may possibly originate on species such as this related to the banana. An account is also given in the paper of the development of the disease in sites which had been replanted after previous infection and abandonment. New cases may arise both spontaneously and in association with pre-existing ones, the rate of appearance of each type tending to decline after an initial rise. Although, on the evidence, *F. oxysporum f. cubense* only survives for a relatively short period in infected plant material, owing to rapid decay, it nevertheless survives for many years in the soil. A marked increase in the population of the pathogen takes place a few months after wilt disease appears, but there is a decline after infected plants are removed. Wide variation was found in the ratio of non-pathogenic to pathogenic strains of *F. oxysporum* in soils, but it is usually very high. The possible mode of survival of the pathogen in soil is discussed.

### *Forestry Abstracts*

FORESTRY is a science of region-wide husbandry and land use, and the training of the forester is based on many sciences; for example, he must survey and map both from the ground and the air, be able to construct, and certainly maintain, roads, bridges, cable-ways and buildings, and handle specialized machinery. These are in addition to his interest in his major object—the production of wood—which takes him a long way into applied biology, genetics, physics, mechanics and chemistry. In a recent number of *Forestry Abstracts* (16, No. 2; 1955; Commonwealth Forestry Bureau, Oxford) an article entitled "The Literature of Forestry: an Appraisal" gives the aims and objects of the *Abstracts*. "In view of its primary function—to act as an effective clearing-house of information for scientists and research workers . . . in forestry—ready access to all of the relevant literature is a constant basic objective of this and of every Bureau of the Commonwealth Agricultural Bureaux Organization. In the world of to-day, with scientific publishing an ill-ordered jungle, and procurement aggravated by post-war political barriers, such an object must remain impossible of attainment." In consequence, material of value to the forester's work must be watched for in a very wide range of non-forestry publications, from a microscopists' journal to the monograph in applied chemistry (of course, these difficulties are shared in varying measure by other sciences). A century ago, there was very little forestry literature published in the English language. The great expansion has taken place during the present century; the most important part, but by no means the whole, is published in the bulletins, reports, etc., issued by research centres and in the leading scientific periodicals. In the article in *Forestry Abstracts* some interesting figures are given of the great increase in the mass of literature both in volume and variety of origin since the Second World War. In January 1947 periodicals numbered 379 and serial sets (including annual reports) 470; total 849. In January 1955, periodicals were 555 and serial sets 755; total 1,310. This mass of publications originated from nearly a hundred countries with more than thirty languages.

### Madrid Observatory Almanac for 1955

A COMPARISON of "The Nautical Almanac" with the "Anuario del Observatorio Astronómico de Madrid para 1955" (pp. 429 + 2 plates. Madrid: Observatorio Astronómico, 1954; 40 pesetas) shows that, while practically the same ground is covered by each, the Spanish publication contains some additional matter which will prove useful to astronomers in other countries. In general, the "Anuario", which is published under the direction of Sr. Martin Lorón, follows the plan that has been in use for some years. Among the additional matter may be noticed a list of forty-four periodic comets which have been observed from 467 B.C. up to A.D. 1942, the first of these being Halley's Comet and the last Comet Oterma. This is followed by a catalogue of the principal constellations, arranged in order of their right ascensions, then by another catalogue of clusters and nebulæ visible from Spain, and also one of double stars. The geographical positions of the chief observatories are given, after which there are 113 pages dealing with visual double stars. This section commences with a short historical sketch, starting with Riccioli's description in 1650 of ζ Urs. Maj., and including an account of the work done by various observers in this branch of astronomy up to recent times. Methods of observation, measurements by means of the interferometer, Hargreaves's comparison micrometer with diagrams explanatory of the principle, etc., are dealt with, and the section ends with a description, covering fifty pages, of the method of determination of binary orbits. This includes two tables for facilitating the computations, and everyone interested in the computation of the orbits of binaries will find this portion very helpful.

### Origin of Stellar Systems and Planets

A LONG article by Alexandre Dauvillier, dealing with the origin of galaxies, planetary systems, satellites, comets, etc. (l'origine de la terre, systèmes stellaires et planétaires: structure et origine), is to be found in *La Revue Scientifique* (No. 3324, July–December 1953), the article being based on an annual inaugural address of the course of cosmic physics given at the Collège de France, Paris; those interested in problems of cosmology will find much in it of considerable importance. The formation of planetary systems is, according to Dauvillier, merely a particular case of stellar interactions, resulting generally in the formation of double and multiple stars. It is estimated that our Galaxy must contain at the least two thousand million planetary systems, though many of the planets may have very eccentric orbits resembling those of comets; others may have planets more massive than Jupiter, and many other variations from what we find in our solar system are inevitable.

### Postgraduate Awards in British Commonwealth Universities

THE Association of Universities of the British Commonwealth has issued as a separate pamphlet Appendixes II and III of the Commonwealth Universities Yearbook, 1955 (pp. 117: from the Association at 36 Gordon Square, London, W.C.1). The first of these, which is printed in accordance with a resolution of the Congress of Universities of the Commonwealth in July 1948, lists postgraduate awards for advanced study and research tenable in the United Kingdom. Each award is differentiated in respect of eligibility for graduates of universities in the United Kingdom, graduates of British universities overseas, and graduates of universities outside the British Commonwealth. The awards are arranged by subject, and those open only to graduates of the university announcing it are not included. Appendix III lists similarly some of the more important postgraduate awards tenable overseas by British graduates, but does not claim to be exhaustive; it is intended primarily for United Kingdom graduates wishing to study abroad. The pamphlet is well printed and produced and constitutes a most convenient pocket reference work. Reference is made to other publications of similar type.

## Paris Academy of Sciences

The following elections have been made by the Paris Academy of Sciences: Prof. R. de Malleman, professor of physics in the University of Nancy, to be a non-resident member in succession to the late Dr. P. Teilhard de Chardin; Prof. G. Darmois, professor of mathematics in the University of Paris, to be member of the Astronomy Section in succession to the late Dr. J. Chazy; Prof. E. Gaumann, professor of plant pathology in the Swiss Federal Institute of Technology, Zurich, and Prof. A. Blalock, professor of surgery in the Johns Hopkins University, Baltimore, to be foreign associates in succession to the late Prof. A. F. Blakeslee and the late Sir Alexander Fleming, respectively.

## Eighth Science Congress of the Royal Society of New Zealand

The report of the Eighth Science Congress of the Royal Society of New Zealand, held at Auckland during May 17–21, 1954, has now been published as Part 4 of Vol. 82 of the Society's *Transactions* (pp. 150. Wellington: Royal Society of New Zealand, 1955). Besides the presidential address of Dr. W. B. B. Oliver, on "Changes in the Flora and Fauna of New Zealand", it includes the addresses of the chairmen of the various sections, with the exception of Section J (Anthropology), which is given only in abstract. Also published in the report are the two public lectures: that of Prof. M. L. E. Oliphant on "Science and Mankind", and that of Dr. R. N. Robertson on "The Struggle against Equilibrium—a Physico-Chemical Problem in Life". Prof. Oliphant's examination of the foundations of scientific activity, the part it now plays in any developed community and where it is likely to lead, is of very general interest; and his comments on the use and misuse of knowledge, particularly with reference to nuclear physics, are highly pertinent to current discussions on nuclear weapons and nuclear power. A number of chairmen's addresses are also of general interest, notably Prof. E. Beaglehole's discussion of the study of social change in relation to the administration of programmes of technical assistance, that of Dr. M. M. Burns on "Agricultural Science: Contributions and Challenges", and, to a lesser extent, Mr. J. L. King's discussion of the relative problems of the two professions of architecture and engineering. The contributions of Dr. H. O. Askew on biology and the trace elements, of Dr. R. C. Lister on rural settlement, with examples from Canterbury and Southland, and of Mr. N. H. Taylor on the role of soil science in New Zealand problems, are more specialized but still of some general interest, and are presented in a way which will appeal to the general public.

## Announcements

Dr. R. L. Smith-Rose, director of radio research in the Department of Scientific and Industrial Research, has been appointed acting director of the National Physical Laboratory, following the resignation of Sir Edward Bullard and pending the appointment of a new director.

Dr. Detlev Bronk, O.B.E., For.Mem.R.S., president of the Rockefeller Institute and of the U.S. National Academy of Sciences, has been appointed chairman of the Board of the U.S. National Science Foundation.

Mr. K. J. B. Wolfe, formerly deputy director of research for the B.S.A. Company, Ltd., and chief metallurgist, B.S.A. Tools Group of Companies, has been appointed head of fundamental research by the Triplex Safety Glass Co., Ltd., and will take charge of the company's new research department to be built at its Willesden factory in West London.

The Cigar Manufacturers Association of America, in conjunction with the Cigar Institute of America, has made this year's Cigar Industry Annual Research Award to Dr. Walter G. Frankenburg, of Lancaster, Pennsylvania, in recognition of his outstanding contributions to the development of the basic science and technology of tobacco; in particular, for his investigations of the chemical processes that occur in the harvested tobacco leaf, including the conversion of nicotine into a series of other substances, and for the successful application of this new knowledge to problems of the cigar industry. The Award is open to persons engaged in research on the chemistry, biochemistry, biophysics, physiology or agronomy of cigar tobaccos. Consideration for the next Award will be given to all communications submitted to the Chairman, Industry Committee on Awards, Room 2214, 350 Fifth Avenue, New York 1, N.Y.

Erratum.—Referring to the article "Acceleration of Abscission by a Factor produced in Senescent Leaves", by Dr. Daphne J. Osborne (*Nature*, December 17, p. 1161), the author writes that in Table 1, the figure 55 in the second column from the left should be 65. Moreover, a cursory glance at the table might lead the reader to suppose that all the data refer to one experiment rather than to four. To avoid this, the following table should be substituted:

Table 1 Average time in hours for abscission of bean explants when (*a*) agar blocks containing diffusates from young or abscinded pulvini are applied to the pulvinar end; or (*b*) whole pulvini are sealed with agar to the pulvinar end

| | (*a*) | | | | (*b*) | | |
|---|---|---|---|---|---|---|---|
| | Control | Diffusate from young pulvini | Diffusate from abscinded pulvini | | Control | Pulvini from attached leaves | Pulvini from abscinded leaves |
| Expt. 1 | 107 | 105 | 88 | Expt. 3 | >120 | 55 (from senescent leaves) | 45 |
| Expt. 2 | 61 | 65 | 53 | Expt. 4 | 57 | 56 (from young leaves) | 37 |

# WELLCOME MUSEUMS AT THE ROYAL COLLEGE OF SURGEONS

THE Wellcome Museums of the Royal College of Surgeons of England were formally opened on November 30 by Sir Henry Dale, chairman of the Wellcome Trustees. The ceremony took place in the Great Hall of the College, situated immediately beneath the Museums, and the gift was accepted on behalf of the College by the president, Sir Harry Platt.

The erection of the Museums has been made possible by a generous gift of £100,000 to the College by the Wellcome Trustees. The grant was made in recognition of the service which the College has rendered not only to surgery but also to a much wider range of medical and scientific knowledge by the maintenance of its historic and world-famous museums of human and comparative anatomy and pathology. In accordance with the terms of the Trust, the grant was "for the foundation or extension of Museums dealing with medical science or research", a description which was in accordance with the policy of the College Council, which has for long regarded its museums and research laboratories as complementary to each other.

The further condition that the name of Wellcome should be associated with the Museums was one with which the College was happy to comply, for the late Sir Henry Wellcome was an honorary fellow of the College.

The Museums are contained in the south-eastern part of the College, the first part to be rebuilt and enlarged after war damage in 1941. They are situated on the second, third and fourth floors, lying immediately above the Great Hall and coinciding with it in area. The general plan is the same on each floor, the main area (about five-sevenths) forming the exhibition room and the remainder being devoted to research and work-rooms connected with the respective museum functions. Adjacent are the other parts of the College's Departments of Pathology and Anatomy, with their research laboratories and (yet to be built) demonstration rooms. Thus on each floor the Wellcome Museum forms an integral part of the department, the threefold activities of which, dealing with museum, research and teaching, are co-ordinated by the Sir William Collins professor of human and comparative anatomy and conservator of the Anatomical Museum and by the Sir William Collins professor of human and comparative pathology and conservator of the Pathological Museum.

On the second floor the approach is through the research rooms of the Department of Pathology and the offices of the conservator (Prof. G. J. Cunningham). The Wellcome rooms begin with the office of the pathology curator (Dr. L. W. Proger), adjacent to which is a research laboratory and opposite is a museum preparation room and workshop. The exhibition room itself shows the layout intended for all three museums, namely, five bays along either side of the room, each containing specimen shelves on three sides and a table and chairs for study in the centre. The central aisle of the room can be laid out with floor stands or left free for temporary exhibitions. 'Natural' fluorescent lighting has been provided, and this with the neutral grey background displays the colour of the specimens to best advantage.

The present collection is made up of specimens surviving war damage, together with more recent additions. The specimens are arranged in lettered sections according to systems: S, skeletal; A, alimentary; etc. Catalogues with descriptions, clinical and histological notes are provided, and reference to histological slides may be made if required. In suitable cases, photomicrographs, X-rays or clinical photographs are mounted with the specimen to complete the pathological picture. Future progress with this collection involves improving quality, extending the series of exhibits and making good deficiencies.

On the third floor the approach is similarly through the research rooms of the Department of Pathology, though the rooms on this floor are temporarily let to the Imperial Cancer Research Fund as biochemical laboratories. The Wellcome rooms on the third floor start with the photographic studio unit and a large museum store. In the exhibition room the arrangement of the shelves at the near end is similar to that of the room below, while at the farther end a space has been partitioned off, by agreement with the Wellcome Trustees, as a demonstration room for students taking the Basic Medical Sciences course. This is a temporary arrangement, pending completion of the next phase of rebuilding the College, and the whole room will be devoted to the exhibition of specimens within the space of two or three years. The present exhibits include the Teratology Section and selections from the Odontological Collection, the War Collection, and Hunterian Collection. On completion of the next phase of the rebuilding programme, this room will be devoted to a museum illustrating the general principles of pathology. In this collection provision will be made to supplement the specimens with photographs, charts and diagrams.

The fourth floor forms a part of the Department of Anatomy, and here again the approach is through the research rooms and the offices of the conservator (Prof. G. W. Causey). As on the other floors, the Wellcome rooms are reached just before the exhibition room and include a workshop and mounting room, an embalming and preparation room and a prosectors' room. The room at present used for prosectors is destined eventually to become the curator's room.

The exhibition room itself, the Museum of Anatomy and Physiology, is eventually to be laid out with bays on very much the same plan as that of the second floor. Meanwhile, however, the Wellcome Trustees have generously agreed to accommodate the College during its rebuilding by allowing demonstrations to be held in the Museum. Two rooms have therefore been formed by the erection of light partitions, and steel shelving has been put up as a temporary arrangement on all the available wall space.

The first part of the exhibition room contains the Hunterian Physiological and Comparative Anatomical Collection that will be ultimately housed in the rebuilt west end of the College. The far end of the exhibition room contains the human anatomical specimens that will later be arranged in cubicles covering different systems, illustrated by suitable tracings and diagrams of selected physiological and pharmacological reactions.

These new Museums occupy nearly the same site as the rooms which were destroyed by enemy action in 1941, though they are at a higher level and are more economical of space, each occupying one complete story, compared with the nineteenth-century rooms which consisted of a floor and two galleries.

---

# THE NATIONAL LEATHERSELLERS COLLEGE

By Dr. J. P. DANBY

Principal

On November 15, the Minister of Education opened extensions at the National Leathersellers College in Bermondsey, London, S.E.1. These consist of a three-story wing housing new research laboratories, a lecture theatre and a senior common room, and drying rooms for heavy and light leather, together with a single-story block consisting of yards for the preliminary and tanning processes for both heavy and light leather manufacture. Moreover, the additional space provided has facilitated the re-equipment and modernization of the original building, which is now almost fifty years old.

The College was founded and built in 1909 by the Worshipful Company of Leathersellers, following the success of the courses in leather manufacture which had been given since 1895 at the Herolds Institute. During these years, rapid developments were taking place in the field of leather chemistry, and it was becoming apparent that the subject merited individual facilities for training and research. The appreciation of fundamental principles underlying the processes of a craft industry by men such as Procter, Stiasny and Knapp was raising leather manufacture from a craft to a science, with the consequence that a rapid expansion took place in the demand for men with a scientific training by tanners all over the world.

Between 1909 and 1951 the Leathersellers Technical College became recognized throughout the world as one of the leading institutions in this sphere of instruction, and under three successive principals gained a wide reputation for the training of technologists in the leather industry. However, although improvements and additions to the College were made from time to time, it was inevitable that sooner or later major developments would be necessary if the College were to maintain its place in the advance of technological education. Consequently, when the Minister of Education, following the recommendations of the Percy Report, decided to found a number of colleges with national status to accommodate the educational needs of the smaller industries, the leather industry approached him with the request that the Leathersellers College should be reconstituted as the National College for the Leather Industry. A trust deed was drawn up, a widely representative board of governors was appointed, and the National College came into being in September 1951. Shortly afterwards, plans were drawn up to extend and re-equip the College, and this has now been done at a cost of more than £90,000, a part of which has been provided by the industry itself. In consequence, there is little doubt that the College is now one of the finest of its kind in the world.

Since the tanner's raw material is animal skins, the technology of leather manufacture is based on protein chemistry. At the same time, because of the variety of other materials used in the manufacturing processes, a trained technologist must possess some knowledge of a wider range of both natural and synthetic products than is called for by almost any other industry, and the subject has therefore some connexion with all the main branches of pure, and many aspects of applied, chemistry. From the practical point of view also, the range of leathers in common use necessitates, in a teaching institution, facilities for their manufacture from the raw skin to the finished product. Further, some familiarity with the ancillary subjects becomes necessary in so far as they impinge on both the theoretical and practical aspects of the principal study.

The scientific and practical approaches have always been the foundations of the College courses; although in the past the training has been more squarely based on processes than on theory, the latter has by no means been neglected. However, the advances which have been made in fundamental knowledge and its systematization, and the development of new techniques, now demand a far more exhaustive course than it has been possible to provide hitherto, and the extensions and modernization have consequently made possible an appropriate and overdue expansion of the content of the syllabus. Moreover, in formulating educational policy, the intentions of the Ministry with respect to academic status have been observed in that plans have been made to bring by stages the level of instruction up to that of a university.

The material facilities the College possesses are unique in so far as that, for practical instruction, they include complete yards for the manufacture of all types of leather, which are made by students working independently, under supervision, as part of their course. The layout has been planned to simulate ideal tannery conditions, and the machinery and other equipment, much of it supplied on permanent loan by the makers, is of the latest design. It will be possible to process twelve hides per week, and in the more flexible conditions of light-leather manufacture, at least twelve dozen skins, by any of the commercial—and many of the experimental—techniques available. A further feature of this department is a complete set of new drying cabinets controlled for humidity, temperature and air-flow, incorporating devices which have been developed over the past decade. All the practical processing work can be now carried out on the ground-floor, which in effect contains a complete tannery appreciably larger than a typical pilot plant.

The additional laboratory space comprises a newly equipped teaching laboratory for senior students, and a microbiological laboratory. Another laboratory has been furnished for physical testing, and it is hoped that in time this will house the most complete set of apparatus for this purpose in Britain. These are, however, extensions of facilities that existed in the original building. An entirely new addition is a research laboratory, which includes a small laboratory-tannery that is to be used mainly for investigations into variations in the processes of the production of sole leather.

The College awards its own diploma on a two-year course, but an extension of this period to one of three years is envisaged to accommodate adequately the increased practical and theoretical instruction made necessary by recent advances in such techniques as leather dyeing, tanning with synthetic materials, drying and so forth. Moreover, in response to the Ministry's expressed intentions with regard to national colleges, the status of the diploma course is to be raised in respect to the level of the training it provides. Although the diploma is a qualification recognized throughout the world in leather-producing circles, it does not possess the standing of a degree, and therefore the outcome of the protracted discussions on higher awards for technology is, as in all similar colleges, awaited with some impatience.

The College offers its own associateship, which may be awarded after a year's research subsequent to the diploma, or to a graduate of a recognized university after a similar period of study. The provision of new research facilities is the most notable innovation under the extension scheme, and it is worth remarking that all the stages of a research programme, from the bench through pilot-plant scale production to what is almost full-scale production, is here housed under one roof. It is therefore proposed to encourage this aspect of the College's activities more vigorously than in the past, and to seek the co-operation of tanners and chemical manufacturers in the matter. Co-operation already exists between the College and the research associations, and the Leather Department in the University of Leeds, so that in this connexion also the Ministry's recommendations are being implemented.

Outside the diploma course, as much flexibility as possible is permitted, notably in the provision of short courses of three or six months duration on specialized aspects of the subject, and, within the confines of space and staff available, every effort is made to accept students individually for courses of even shorter duration. Short refresher courses of from four to six weeks have been a feature since 1951, and these are to be extended, especially in relation to the ancillary sciences. Entirely new courses on works and management study in the leather trade are planned, as part of the normal diploma course, in addition to being offered to the industry as a whole.

The College draws its students from all over the world, and although a quota is placed on entrants from outside the United Kingdom, the fact is evidence of the wide reputation it has gained since its foundation. There is a generous staff–student ratio, and with the space now available, and the promise of adequate support from the trade, it is anticipated that the College will play an increasingly important part in the industry to which it belongs.

# FIRST NATIONAL CROP PROTECTION CONFERENCE

The first National Crop Protection Conference, sponsored by the Pesticides Group of the Society of Chemical Industry and organized in collaboration with the Ministry of Agriculture, Fisheries and Food, the Association of British Insecticide Manufacturers, the British Agricultural Contractors Association, the National Association of Corn and Agricultural Merchants, and the National Farmers Union, was held in the Winter Gardens, Eastbourne, during October 31–November 3. The theme of the Conference was: "Practical Aspects of the Use of Insecticides and Fungicides in Agriculture and Horticulture". The delegates assembled on the evening of October 31 for the chairman's reception at the Grand Hotel, Eastbourne, and later attended a film show, at which were shown "Management for Milk" (Plant Protection), "Fruit Tree Red Spider" (Shell), "Cabbage Root Fly" (Shell) and "The Rival World" (Shell). The last, a dramatic film illustrating man's ceaseless battle not only for food but also for health and very survival against the insect world, underlined the theme of the Conference during the following days. The Conference proper commenced on the following day, when a short account was given by the chairman, Mr. J. M. Leonard, of the Society of Chemical Industry, of the formation of the Pesticides Group and of the events leading up to the holding of the present meeting. Starting with the formation of the Agricultural Group of the Society in 1942, which gave birth to the Pesticides Panel in 1950, he told how the Panel had itself become a group by 1954, capable of sponsoring the Conference by 1955, which was no mean achievement.

The opening address to the Conference was given by Sir Thomas Dugdale, who touched upon the world's loss of produce to pests, both in the field and in storage. These are serious enough in highly developed countries, but in the less-developed ones they must be very much more serious. Since 1940 there have been enormous strides made in the science —and art—of dealing with crop pests; but looking back he saw many landmarks in crop protection and wondered if there might be such a thing as a "fifteen-year rule" in these developments. Before 1940, the start of the present cycle, tar-oil winter wash for fruit trees was introduced about 1925. Derris arrived in 1910. Lime-sulphur and grease banding was brought in about 1895. Still earlier, in 1880, there are records of 'London purple' (an arsenical) being exported to the United States. Before the Second World War, links between the manufacturers and the 'official' research stations were slender and few, and differences many, leading to bewilderment on the part of the farmer; now Sir Thomas sees a much healthier state of interaction from which the farmer is not excluded; the Ministry of Agriculture's Approval Scheme has also marked a great advance. He defined four main groups of pesticides: insecticides and acaricides; fungicides; nematicides; and herbicides. Substances for the control of birds and rodents—mostly the latter—may perhaps be considered as a fifth group. The important points to be remembered are that the use of pesticides must be governed by economics, and that chemicals must not be used as substitutes for good farming. Turning to the future, Sir Thomas asked what scientists have in store for us. Would the fifteen-year rule hold good? Will systematic fungicides really abolish plant disease? Would the only red spiders left be those in museums? Or would Nature fill the vacuum she abhorred? There are already a number of pests which have increased in importance due to the elimination of predators by pesticides; one answer to this is the use of more selective insecticides and methods of application. Flies resistant to the chlorinated hydrocarbon types of insecticide are already a challenge in many places. So long, however, as the problems are attacked bearing in mind these consequences of large-scale interference with Nature, nothing but good can come of the scientists' work.

The first three papers at the Conference were on general subjects. In a general survey of eelworm problems, Dr. B. G. Peters dealt in broad terms with these insidious pests, which are often not detected until extensive damage has been caused. A general survey of soil pests affecting vegetable crops, by Mr. J. W. Wright, was the subject of the following paper, and a general survey on foliage diseases in arable crops, by Dr. H. E. Croxall, rounded off these introductory talks. Later papers dealt with more specialized aspects. In considering the economics of potato blight control, Mr. H. I. Kingston dealt with the search for substitutes to replace the now very expensive copper compounds, and it appears that small quantities of phenyl mercuric chloride can act as synergists and effect reductions in the use of copper up to 40 per cent. In a paper on virus problems in sugar beet, Dr. R. Hull told how loss due to this disease has been reduced in recent years, thanks to careful rogueing on steckling beds and liberal use of insecticides, especially the systemics. The last two papers of the day, control of pests in arable crops, by Mr. J. L. Hunt, and control of pests in *Brassica* seed crops, by Mr. S. G. Jary, drew much discussion on matters ranging from the forecasting of pest incidence to the amount of loss which can be suffered by seed brassicas without reduction of eventual yield.

The morning of November 2 was devoted to a series of papers on application problems and hazards. The application of materials to control pests and diseases of pea crops was dealt with by Mr. R. W. Shorrock and provoked a lively discussion, in which many references were made to the increasing recognition of eelworm as a widespread pest of this crop. The next paper, by Mr. F. W. Morris, on the advantages of high- versus low-volume spraying, was another which led to considerable controversy. Mr. Cameron Gifford, speaking on application aspects of aphis control in sugar beet, brassicas and related crops, emphasized the case for dusting in certain instances. Hazards were dealt with by Dr. E. F. Edson and Dr. J. M. Barnes for application and residue problems, respectively, in a pair of most interesting papers in which emphasis was laid upon the desirability of education for safety rather than 'blanket' legislation. The meeting then passed to consideration of seed dressings. Recent developments in the use and application of dual-purpose seed dressings—that is, of insecticide and fungicide seed dressings—was the subject of a review by Dr. D. Price Jones, and Mr. A. J. Pearson, in a paper on 'Dieldrin' seed dressings, described trials of this comparatively new insecticide against insect pests of the seed and seedling. Taint was discussed by Dr. M. Cohen, who described not only the cases of taint, in which benzene hexachloride is still the principal offender, but also the form of tests used for estimation of off-flavours. Dr. R. de B. Ashworth then gave an account of groups of new chemicals recently included in the crop-protection products approvals scheme.

The last day of the Conference opened with a consideration of glass-house problems. The first paper, by Dr. E. Taylor, dealt with the control of fungi under glass, and was followed by one on control of insects under glass, read by Mr. W. H. Read. The glass-house crops can be more efficiently dealt with by fumigation and aerosol methods than those out of doors, but, on the other hand, their concentration within small spaces raises a number of its own problems. The remainder of the day was occupied with horticultural problems. Mr. J. E. Garnham, speaking on control of red spider on fruit, described the use of chlorbenside against this serious pest, emphasizing the importance of its application early against winter eggs and immature mites, and condemned the use of the term 'ovicide' when applied to such a widely active compound. In considering the control of fruit pests other than red spider, Mr. E. L. Williams directed attention to the increasing use of insecticide sprays for pests against which winter washing used to be the standard treatment. In the ensuing discussion many suggestions were put forward for reducing the number of separate spraying operations by mixed applications of insecticides and fungicides. New techniques for the control of pests on hops were described by Mr. Emery, who showed some very spectacular slides on the effect of the insecticide dimefox applied to the soil beneath the bines. In reply to questions, he mentioned experiments showing first that the quantity of dimefox present in the hops on harvest is negligible, and secondly, that any which is present would certainly be destroyed in the process of brewing. Mr. E. J. Hainsworth then read a paper on recent advances in scab control, from which it appears that the growing use of captan and the organo-mercurials calls for discretion and that there is still a case to be made out for the use of sulphur. The final paper, on other aspects of the control of fungus diseases on fruit, by Mr. R. W. Marsh, stressed the inability of the newer scab-controlling insecticides to keep down the mildews which are at present controlled by means of sulphur sprays. He also spoke of experiments using phenyl mercuric chloride against apple tree canker.

# IONIZING RADIATION AND THE CELL

A SERIES of fourteen papers and an introduction by G. Pollard, which were presented at a conference of the New York Academy of Sciences on "Ionizing Radiation and the Cell", have now been collected as a separate issue of the Academy's *Annals* (59, Art. 3, 467–664; 1955; 4 dollars). For a very good reason the major part of this volume should be of absorbing interest for biologists in a number of different fields. It shows in a precise way, yet intelligible to those outside radiation biology, how varied are the methods now available which use ionizing radiations for analysing ultramicroscopic biological structures and their functions. This is more than can be said of the often ponderous other publications on radiation biology which have multiplied in recent years.

The essentials of the oldest and best-known radiation method are that localized releases of energy within a cell structure may cause it to lose or change one or more of its biological functions. Comparing loss of function caused by irradiation with different types and doses of radiation, one can infer something about the size, shape and molecular stability of the structures examined, and about the relations of these to function. This type of analysis has given useful results, for example, in the case of the structure and function of bacteriophage particles, of chromosomes and genes, and of various other cellular components. The same sort of analysis has been applied successfully to large molecules: a paper by Setlow illustrates it very effectively for the case of certain enzymes and other proteins.

Several of the papers at this conference are based on the use of this inactivation method: one by Fluke and Pollard on bacteriophage; one by Caldecott on barley; one by Bloom *et al.* on the use of microbeams (2·5–7 μ in diameter) on tissue cultures of newt heart; and others. A paper by Giles *et al.*, however, reports the use of radiation both to produce 'loss' mutations and to reverse them.

An elegant new use of ionizing radiations, introduced by Hutchinson, of the Biophysics Department at Yale University, is for probing structure by a sort of radiation sounding procedure. With charged particles such as electrons and protons in beams of controlled energy, it is possible to irradiate the outer layers of a biological system without producing any effect at a depth greater than the particle-range. This range varies in a known way with the kind and energy of the particles. Thus, by using a series of beams of increasing energy, one can probe deeper and deeper into the system. When this is done, discontinuity of structure may become quite clear. For example, inactivation of bacteriophage *T*-1 with slow electrons shows a steep rise between 700 and 1,100 volts, and from this Hutchinson calculates that there is an insensitive outer layer about 125 A. thick. This finding is in perfect agreement with those from the biochemistry and genetics of this phage, which is known to have a protein coating not essential for its multiplication, and an essential core of deoxyribonucleic acid.

All the other papers in this volume are well worth reading by the specialist, though perhaps for the non-specialist they are not as important as those already quoted.

G. PONTECORVO

# THE MELLON INSTITUTE

## REPORT FOR 1954

THE annual report* of the president, Dr. E. R. Weidlein, to the Board of Trustees of the Mellon Institute on the scientific research activities of the Institute for the year ended February 28, 1955, notes the establishment of a new Department of Applied Mathematics to assist in formulating experimental designs and the statistical analysis of data, the installation of an electron microscope in the Department of Research in Chemical Physics, and the equipment of an air-conditioned laboratory for microchemical analysis and research in the Department of Analytical Chemistry. Expenditure on pure and applied research during the year was 4,784,344 dollars, and, of this sum, just over a million dollars was spent on scientific research in the six research departments and on twelve fellowships, in which altogether 147 members of the Institute were engaged. Applied research was conducted under the auspices of sixty-four other fellowships and occupied the time of 390 members. Of these seventy-six fellowships, forty-seven were multiple and twenty-nine individual, and four had been proceeding for forty years and four others for thirty or more years.

Investigations in the Department of Research in Chemical Physics of the selection rules for ethane-like molecules having free internal rotation showed that the selection rules were $D_{3d}$ and not $D_{3h}$ as reported in the literature. The vibrational spectrum alone does not distinguish between the alternatives of free internal rotation or the staggered configuration. Other investigations showed that in the systems hydrogen chloride – diphenyl ether and hydrogen chloride – anisole at 30–90° C., while the frequency of the hydrogen chloride bond remains constant, its intensity diminishes as the temperature increases. Investigations of crystallization in stretched polybutadiene and silicones continued, and an X-ray diffraction study of the crystal structure of antimony pentachloride showed that the unit cell is hexagonal and contains two molecules of antimony pentachloride, the trigonal bipyramidal structure of the gaseous molecule being retained in the solid state.

Equipment for separation by thermal diffusion and chromatography has been extended in the Department of Research in Physical Chemistry, and further studies of the design and operation of packed laboratory apparatus for fractionation by thermal diffusion include the effect of packing density and annular width on separating efficiency. Elution chromatography on alumina with graded eluents has been used extensively in the separation of coal tar by-products, and separate determinations, in which the cuts were examined by ultra-violet spectroscopy, indicated that a naphthalene still residue carcinogenic to mice contained not more than 0·005 per cent of 3 : 4-benzpyrene. An apparatus built for vapour-phase chromatographic investigations has given effective separations and analyses of hydrocarbon mixtures in the range $C_4$ to $C_8$.

The Department of Instrumentation notes a considerable increase in electronic construction and maintenance activities, and has also designed an automatic recording Sward rocker device and an automatic recording instrument for measuring the surface tension of liquids. The preliminary model of a recording balance designed to deflect a recording potentiometer full scale for a 100-mgm. change in weight has been found to be capable of being operated at ten thousand times this sensitivity before drift and short-term instability become appreciable. In devising a set of classical equations for the hydraulics of column and plate distillation, the Department of Applied Mathematics found that, for a critical value of the ratio of thickness of liquid layer to radius of cylinder, the mass vapour transport per unit area attained a maximum before the onset of turbulence, which indicates a flooding condition in distillation columns with diameters less than a critical value depending on the viscosity and density of the liquid and vapour.

In co-operation with the Multiple Fellowship on Petroleum, the Department of Analytical Chemistry has been engaged for nearly two years in a fundamental study of the analytical chemistry of organic sulphur compounds; in the course of this a revised Hastings method for the determination of aliphatic sulphides in the analysis of crude oils, by spectrophotometric measurement of the absorptivity of the iodine-sulphide complex, and a modified polarographic method for the determination of elemental sulphur have been developed, and the reduction of heteropoly acids with thiols have been studied. An investigation of the degradation of cellulosic fibres showed that the deterioration of certain fibres depended on the cellulolytic activity of the micro-organisms brought in on the raw material and which had proliferated during storage. Fundamental studies of the synthetic autotropic bacterium isolated from bituminous coal-mine effluents continued.

---

* Scientific Research Activities of the Mellon Institute, 1954–55. (Annual Report Series, No. 42.) Pp. v+53. (Pittsburgh: Mellon Institute, 1955.)

Reviewing the work carried out under the Fellowships in Pure Science, the report refers to the major research programme on air pollution of the American Petroleum Institute, in which two laboratory techniques for tracing the path of stack gases over long distances were ready for field-trial. Attention was also being given to the design of simple field-characteristics of dust removal in various centrifugal and gravity sedimentation devices. The exposure phase of a two-year programme to evaluate the potential response to various inorganic particles of different ranges of size was completed, and histopathological examination of the tissues of exposed animals was in progress. Field-studies included the evaluation of the potential dust exposure to a specific product when used industrially as an oil absorbent. Besides preliminary studies on seventy newly available chemicals that may have economic value, detailed studies were made under the Multiple Fellowship on Chemical Hygiene on fifteen compounds which will reach the public and on eight with which industrial workers only will be in contact.

Using an epoxy resin, fibre-glass cloth and a modified hook, workers under the Multiple Fellowship on Orthopedic Appliances have constructed an appliance which gives the patient essentially the equivalent of a finger and thumb and permits normal wrist motion. Hip, knee and ankle joints have been developed for reliable service where a leg dangles or requires traction, and many experimental appliances have been constructed using nylon or fibre-glass cloth and polyester resins. Under the Fellowship on Mine-Acid Control a report has been presented summarizing the findings of the past eight years and has demonstrated that a seam of coal amenable to recovery by stripping can be removed without acid pollution of adjacent streams. Under the Multiple Fellowship in Glass Science a laboratory has been constructed for nuclear and paramagnetic resonance absorption studies, and attention has been given to the origin of the colour induced in silica glass and quartz by X-rays, γ-rays and neutron irradiation in a nuclear reactor and to the mechanical properties of glassy systems. Under the Allotropy Fellowship a bicyclo-[2 : 2 : 2]-octane has been prepared, this being the simplest molecule with the boat configuration of cyclohexane, both by the Diels–Alder reaction from cyclohexadiene and acrolein and by destructive distillation of magnesium hexahydrohomoterephthalate. A new instrument in which the liquid is continuously sheared between a conical and a flat surface has been developed for determining viscosity over a wide range of rates of shear, and birefringence techniques were being developed as a means of estimating the content of crystallinity in polymers. Durable, colourless synthetic resins have been developed by workers under the Artists' Materials Multiple Fellowship to replace traditionally used natural resins, and a new picture varnish was being evaluated in co-operation with prominent museums. Thermoplastic polymers of the methacrylate class appear to fulfil best the requirements of clarity, solubility, durability and strength. In work on components for digital data-handling systems, special emphasis has been placed on the development of novel methods for making electronic circuits and circuit elements for operating at 200° C. or more.

The greater part of the report is concerned with the research programmes of the Fellowships in Applied Science, and only a few points of more general interest can be mentioned here. Among these are the development of an electromagnetic flowmeter for liquids, which is actuated by the electric potential field generated in the liquid as it moves through a magnetic field, and the considerable progress in studying methods of measurement of consistency of clays for mixing and extruding operations. An improved method has been developed for preparing specimens of castable refractories for use in testing. A co-operative study on grinding wheels showed that compressive stresses up to 100,000 lb./sq. in. can be developed in the surface of quenched and tempered ball-bearing steel by abrasive grinding. The generation of gas on prolonged treatment of silicon carbide with water has been traced to impurities in the grain rather than to silicon carbide itself. Satisfactory methods have been developed for welding manually and automatically the new $T-1$ steel recently developed by the United States Steel Corporation. A concentrated effort to obtain 'Stypol' resins particularly adapted to specific reinforced plastics applications has yielded several new resins of unique properties. A long-term biochemical research project is concerned with the basic mechanism of the natural origin of tastes and odours in public water supplies.

Considerable progress was made in the synthesis and study of pyrrole derivatives in petroleum and related materials, and it has been established that oxides of nitrogen produced in the engine during combustion play an important part in the formation of low-temperature engine varnish. Hydrogenation of nitrobenzene to aniline in the vapour phase proceeds at atmospheric pressure over nickel sulphide catalysts, and a comprehensive investigation of catalysts for this reduction has been planned. A unique class of polysaccharides, resembling tapioca dextrins and natural gums, has been synthesized, which shows promise as envelope and label re-moistening gums, as replacements for gum arabic in mucilage and lithography, and as extenders for polyvinyl alcohol. Progress was also made in developing industrial applications for methylglucoside, now being manufactured from corn sugar. Under the Multiple Fellowship on Felt a study was being made of the requirements of individual industrial fabrics and methods for achieving the optimum characteristics. The search for improved hydraulic fluids has continued, and a study of catalysts for epoxy-type resins has been undertaken. New plasticizers were evaluated for the preparation of plastisols, and the effect of temperature on the flow properties of vinyl resin plastisols was studied, while silicones have been developed for application to leather and to glassware. Efforts to prepare compounds similar to the new antibiotic, azaserine, which may be resistant to the enzyme in mice, and presumably in man, which destroys azaserine, or which may inhibit the action of the enzyme, are being made, and a series of dyestuffs of antiviral activity has been prepared; but although the dyestuffs were active against many viruses *in vitro*, no favourable *in vivo* effects were observed. Development work on the improvement of manufacturing processes for barbituric acid derivatives, aminophylline and certain local anaesthetics and antiseptics continued under the Amine Fellowship, which also led to the development of a promising new compound, 7-(β-hydroxypropy)-theophylline.

# PAST AND FUTURE TRENDS IN WORLD ECONOMIC DEVELOPMENT

SIR GEORGE NELSON assumed office as president of the Institution of Electrical Engineers on October 6 and delivered his inaugural address on the evening of that day. In this address, Sir George outlined the course of development of the application of electricity to the needs of the community from the time of the inception of the Institution in 1871 to the present day, and he related this development to the main changes of social and economic environment which have taken place in that interval. From the present day, he then viewed the future prospect.

For Great Britain in 1905, the installed capacity of generating plant represented 1/20 kW. per head of population, while for the United States the corresponding figure was 1/12 kW. These figures have risen in the intervening fifty years to ¼ kW. and ¾ kW., respectively. It has been forecast in a paper read at the recent Atomic Energy Conference at Geneva that the next fifty years would see a threefold increase in the total energy consumption of the world. Already, it is recognized that the world's demands for power will very quickly exhaust the conventional sources of energy, in particular the natural fuels; but the solution of this problem is in sight in the utilization of nuclear energy. This growing demand for power, which is reflected in both the increase in world population and the universal urge to improve standards of living, is, however, accompanied by correspondingly increased consumptions of the basic constructional materials.

Some 90 per cent of the world's present population has a standard of living below that of the United States and Great Britain, and it has been estimated that, if the living standard of the whole world were raised instantly to that of Great Britain, the resources of such basic materials as iron and copper would last only twenty-five years. Although such a rate of exhaustion is far outside practical possibility, considerations such as these do indicate an urgent need, namely, that of producing synthetically basic metals and similar materials.

The most notable development up to the present time in the field of artificial substitutes is the cellulose products. 'Terylene' fibres, for example, have physical properties comparable with those of steel. It is possible that, in time, means may be found of producing economically a substitute for steel for structural purposes, which would render it possible to conserve iron ore for the manufacture of magnetic or such other special-purpose steels. Synthetic materials have also been produced suitable for the manufacture of pipes for carrying hot, cold or corrosive liquids. Such pipes can serve as a substitute for copper or lead pipes and help to conserve the supplies of these metals.

If a lowering of the standard of living due to the exhaustion of natural resources is to be avoided. intensive effort must be devoted to the production of synthetic substitutes of all kinds, and Sir George pointed out that this effort must be made now. The movement of the whole front of technological advance, whether in the generation of power, the manufacture of synthetic materials, or in the application of automatic methods of production, is dependent upon the supply of scientific workers and technologists. The shortage of scientific man-power is one of the major problems confronting Great Britain and the Commonwealth, and the Institution of Electrical Engineers has its contribution to make towards the solution of the problem.

Sir George reviewed some of the efforts which are being made to increase the intake of suitable young men to the engineering profession. He spoke with appreciation of the film entitled "The Enquiring Mind", which has been produced with the object of attracting the attention of parents and boys to the opportunities for careers in the fields of applied science and technology. It is particularly necessary, he suggested, to attract a great proportion of the young people who at present choose to pursue the Arts. There is also an urgent need for technically qualified men who have natural gifts for management and highest administration. Such qualities are inborn, and the aim should be to develop these natural gifts, when found, in association with a scientific or technical education. Sir George regretted that he could not provide a formula for the early identification of men with this gift, but he suggested that careers masters in schools could make a notable contribution in this connexion.

# YEAST MITOCHONDRIA

## Subcellular Units involved in the Synthesis of Respiratory-Enzymes in Yeast

IN a series of papers from this laboratory published in 1949[1], it was shown that clones of normal yeast during their growth constantly give rise to respiration-deficient mutants ('vegetative mutants') stable in vegetative reproduction. The respiratory deficiency was shown to be due to lack of several enzymes (including cytochrome oxidase) bound, in normal yeast, to particles which can be sedimented by centrifugation, and to behave as a non-Mendelian character in crosses between normal and mutant yeast. It was suggested[2] that the mutation consists in the loss or irreversible functional inactivation of a particulate cytoplasmic auto-reproducing factor, and the question of the possible identity of this factor with subcellular units defined by various biochemical and cytological criteria was discussed.

Our observations have been reproduced and extended by several authors (cf. ref. 3) and have been the subject of several reviews in which our own views concerning the problems of the nature of the mutation giving rise to the 'vegetative mutants' on one hand, and that of the identity of the cytoplasmic factor on the other, have sometimes been misinterpreted. The purpose of the present communication is to restate our position regarding these two problems.

In discussing these problems, the following units, each defined by independent criteria, must be taken into consideration: (*a*) the extrachromosomal genetic factor; (*b*) the respiratory enzymes missing in the mutants (cytochrome *c* oxidase, succinic, reduced diphosphopyridine nucleotide, α-glycerophosphate, cytochrome *c* reductases, cytochromes *a* and *b* [4]); (*c*) the particles sedimentable from a yeast homogenate at *c.* 25,000 *g*; (*d*) the various particles revealed by microscopic observation of stained and unstained yeast cells.

(1) The occurrence of cells shown by genetic tests to contain the cytoplasmic factor but devoid of the respiratory enzymes in a permanent or transitory way ('segregational mutants'[5] and normal yeast grown anaerobically[4,6], respectively) proves that units (*a*) cannot be identical with units (*b*), the synthesis of which they control.

(2) Units (*a*) cannot be identical with the totality of particles (*c*), nor with the totality of either the microsomes or the macrosomes (frequently referred to as mitochondria in the biochemical literature) constituting the sedimentable fraction. This is demonstrated by the fact that the sedimentable fractions isolated from homogenates of respiratory mutants cannot be distinguished by their gross analytical characteristics from the corresponding fractions of normal yeast (ref. 4 and de Robichon-Szulmajster, H., unpublished observations). It remains possible, however, that (*a*) corresponds to a small fraction of (*c*).

(3) In considering now the possible relationship between the cytoplasmic units (*a*) postulated on genetic grounds and the visible cytoplasmic units (*d*), it must first be emphasized that the latter constitute a heterogeneous group comprising mitochondria, refractive granules and possibly other elements. The term 'mitochondria' will be reserved here for cytoplasmic structures characterized by their reactions to fixatives and their stainability by the Altmann and janus green *B* procedures. It appears to us reasonable to accept the view that these bodies carry cytochrome *c* oxidase, and that the localization in the cell of janus green *B* directly indicates the localization of this enzyme, the presence of which is a prerequisite of the staining reaction. The presence of cytochrome *c* oxidase is similarly required for the oxidation of the Nadi reagent. However, contrary to what is often assumed, the localization of indophenol blue does not necessarily reveal the site of its formation, for indophenol blue produced by *in vitro* oxidation of the reagent stains some granules in the cytoplasm of respiratory mutants devoid of cytochrome oxidase[4].

Since mitochondria are the carriers of cytochrome *c* oxidase, and since the respiratory mutants lack this enzyme, it was suggested that the genetic factor (*a*) might be identical with mitochondria and that the mutation consists in the loss or inactivation of the mitochondria with respect to their function in synthesizing cytochrome oxidase. The following communication by Y. Yotsuyanagi convincingly shows that the respiratory mutants do contain mitochondria. If it is assumed that the mitochondrial population is homogeneous, we are therefore left with the following two possibilities: (i) the genetic factor (*a*) is not identical with the mitochondria; (ii) the genetic factor corresponds to the mitochondria and the latter are not lost but functionally inactivated in the mutant.

However, if the mitochondrial population is assumed to be heterogeneous, a third possibility remains open: (iii) the genetic factor corresponds to a small fraction (carrying cytochrome oxidase) of the mitochondrial population, which may be lost in the mutant.

It can thus be seen that the identification of the genetic factor with the visible cell elements confronts us with essentially the same questions as its identification with the components of the sedimentable fraction (*c*).

## Mitochondria and Refractive Granules in the Yeast Cell

The present communication is a summary of a re-investigation, by means of cytological techniques, of the controversial problem of yeast mitochondria, prompted by the hypothesis[1] that these bodies might be identical with the cytoplasmic hereditary factor required for the synthesis of respiratory enzymes in yeast. The preceding communication states this problem in the light of the evidence provided by genetic and biochemical data.

By the routine cytological techniques applied to fixed material (Altmann's method, Heidenhain's hæmatoxylin), we have revealed the presence in yeast cells of cytoplasmic bodies exhibiting features characteristic of mitochondria[2]. We have found also that the configuration of these bodies is subject to considerable variations depending on the physiological state of the yeast (growth phase, culture medium, etc.). Lastly, some technical improvements (vigorous aeration during the staining and rigorous control of the concentration of the stain) have permitted us to demonstrate cytoplasmic bodies vitally stainable by janus green *B*.

The configuration of cytoplasmic structures shown by material stained after fixation manifestly coincides with that revealed by janus green *B* in living cells in the same physiological state (Fig. 1). Therefore, in accordance with the usual cytological definition we shall call these bodies 'mitochondria'.

It has been known for a long time that ordinary, as well as phase-contrast, microscopy permits the observation in unstained yeast cells of highly refractive granules. There is nowadays a tendency to consider these refractive granules as mitochondria[3].

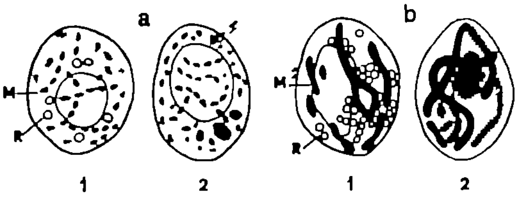

Fig. 1. Pictures of normal yeast cells (strain 'Yeast Foam') obtained by vital staining with janus green *B* (1) and by the application of Altmann's technique (2).
*a* and *b*, cells grown in two different media; *M*, mitochondria; *R*, refractive granules

This tendency is essentially based on the interpretation of images obtained with redox indicators such as indophenol blue and tetrazolium.

However, for the following reasons, the refractive granules seem to constitute quite different entities from the mitochondria as defined above. (*a*) These granules are usually not stained by janus green *B* so long as this reagent is used as a vital stain; (*b*) they differ from mitochondria in their shape, size, number and optical properties; (*c*) double differential staining clearly reveals two different particulate systems present in the cytoplasm; for this purpose yeast is stained vitally in dilute alcoholic solutions of sudan III or in dilute aqueous solutions of tetrazolium and then superstained vitally with janus green *B*. In either case, janus green *B* reveals blue-coloured cytoplasmic bodies, while the refractive granules are stained orange by sudan III or orange to pink by the tetrazolium formazan.

The fact that tetrazolium stains structures differently from those coloured by janus green *B* is of considerable importance. The tetrazolium compounds are frequently considered to be as specific 'mitochondrial stains' as janus green *B*[4]. This interpretation is based more or less implicitly on the following argument: dehydrogenases responsible for the reduction of tetrazolium are bound to particles, and it is assumed that the coloured product of the reduction (formazan) is insoluble in water; it is therefore inferred that the localization of the stain in the cell reveals the localization of particles bearing the dehydrogenases. However, Slonimski has found (unpublished observations) that the formazan of triphenyltetrazolium is soluble in water at very low concentrations (up to 1 p.p.m.) and that the freshly formed formazan is not immediately precipitated. It is clear, therefore, that the diffusion of the product of enzymatic reduction may take place in the cell, and that the localization of the stain may be quite different from the site of its formation. It should be added that both tetrazolium formazan and indophenol blue are soluble in fats, and in many biological materials they stain structures of lipidic nature[5].

In the respiration-deficient strains ('vegetative mutants') of yeast[6], the mitochondrial system is revealed by Altmann's technique. The refractive granules are visible without staining and can be coloured by the reduced tetrazolium. No colour is formed in the presence of janus green *B*, a fact which supports the interpretation[7] that this staining is due to the activity of the cytochrome *c* – cytochrome oxidase system. It is known that the respiration-deficient mutants are devoid of cytochrome *c* oxidase[8]. It appears, therefore, that these mutants contain mitochondria morphologically similar to those of normal yeast, in spite of the fact that they do not contain cytochrome *c* oxidase.

# ENZYMATIC COAGULATION OF SEMEN

By G. GOTTERER, D. GINSBERG, T. SCHULMAN, JULIA BANKS and
DR. H. G. WILLIAMS-ASHMAN*

Ben May Laboratory for Cancer Research, University of Chicago, Chicago 37

THE semen of many species coagulates soon after ejaculation. In the rat and the guinea pig, the vaginal plug which forms after copulation is composed of coagulated semen[2]. Camus and Gley[1,2] were the first to recognize that the secretions of the seminal vesicle were coagulated by an enzyme, designated vesiculase, present in the prostatic secretion of rodents. The classical studies of Walker[3,4] established that this coagulating enzyme is manufactured solely in the anterior prostate or so-called coagulating gland. In man, the coagulated semen afterwards liquefies. Huggins and his collaborators[5,6] have shown quite clearly that the liquefaction of human semen is a proteolytic phenomenon, and that human and other semens contain a number of proteolytic enzymes, a finding which has been confirmed and amplified in the laboratory of Lundquist[7]. However, the nature of the reactions responsible for the coagulation of the semen of any species remains unknown.

A stable preparation of proteins of the seminal vesicle coagulable by vesiculase may be obtained as follows. Fresh secretion of the seminal vesicle of the rat or guinea pig is extracted with 0·15 *M* sodium chloride at 2°, insoluble material is removed by centrifugation, and the saline-soluble proteins are precipitated by the addition of cold acetone to a final concentration of 66 per cent. The precipitate is washed with acetone and dried *in vacuo*. The dry powder is stable for at least one month when it is stored in a desiccator at 2°. The coagulable protein(s) is extracted from the acetone powder with 0·15 *M* sodium chloride at 25°, a small insoluble residue being discarded. Such saline extracts can be separated into three major protein components by electrophoresis in 0·1 *M* barbiturate buffer of *p*H 8·6, or by chromatography on ion exchange resins.

---

* Scholar in Cancer Research of the American Cancer Society.

The coagulation of these proteins of the seminal vesicle by vesiculase can be determined turbidimetrically at 660 mμ. In solutions buffered at *p*H 7·4, the action of vesiculase is dependent upon the concentration of seminal vesicle proteins added, and especially upon the ionic strength of the reaction mixture. If the final concentration of seminal vesicle proteins is 15 mgm. per ml. or greater, and if the ionic strength is in the vicinity of 0·09, coagulation commences soon after the addition of vesiculase. Increasing the ionic strength to approximately 0·13 by the addition of sodium chloride or sodium bromide or potassium chloride induces a pronounced lag period, which is followed by a rapid rate of formation of insoluble protein. Further elevation of the ionic strength increases the duration of the lag period, but has little influence upon the rate of coagulation once it begins, as can be seen from Fig. 1. At ionic strengths of about 0·09, alteration in the amount of vesiculase added affects both the length of the lag period and the rate of coagulation. At ionic strengths of 0·15 or higher, the lag period, but not the rate of change in turbidity, varies inversely with the quantity of enzyme added. This fact is illustrated in Fig. 2, which also shows that increasing the concentration of seminal vesicle proteins decreases the lag period at a given ionic strength. Vesiculase exhibits a broad optimum over the *p*H range of 6·0–8·0. At *p*H 7·4, coagulation takes place equally well in either tris (hydroxymethyl) aminomethane or phosphate buffers provided that the ionic strengths are kept equal.

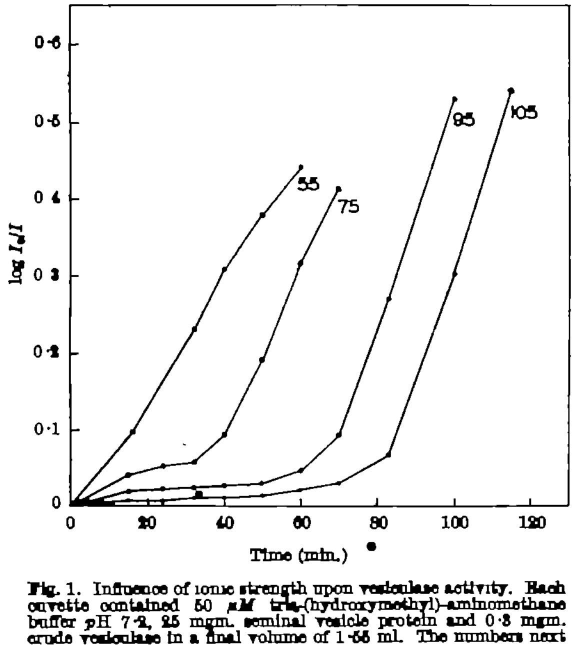

Fig. 1. Influence of ionic strength upon vesiculase activity. Each cuvette contained 50 μ*M* tris-(hydroxymethyl)-aminomethane buffer *p*H 7·2, 25 mgm. seminal vesicle protein and 0·3 mgm. crude vesiculase in a final volume of 1·55 ml. The numbers next to each curve represent the micromoles of sodium chloride per ml. of reaction mixture. Temperature 27°

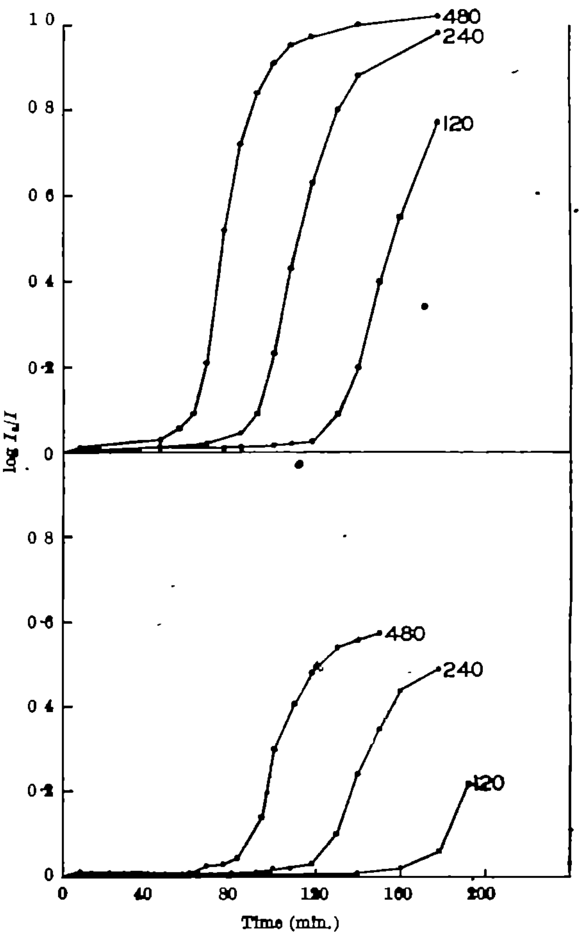

Fig. 2. Influence of the concentration of seminal vesicle protein and of vesiculase upon coagulation. Each cuvette contained 10 μ*M* of sodium phosphate buffer *p*H 7·4 and 165 μ*M* sodium chloride in a final volume of 1 2 ml. The final concentration of seminal vesicle proteins added was 15 and 7·4 mgm. per ml. in the upper and lower series of curves, respectively. The figure next to each curve represents the micrograms of crude vesiculase per ml. of reaction mixture. Temperature 27°

The insoluble material formed by the action of vesiculase upon seminal vesicle proteins is digested by trypsin, but is not soluble in 6·6 *M* urea at *p*H 7 after twenty-four hours at 30°.

The action of either crude or purified vesiculase in tris-(hydroxymethyl)-aminomethane buffer at *p*H 7·4 is unaffected by 2 m*M* concentrations of Ca$^{++}$, Mg$^{++}$ and Mn$^{++}$. It is abolished, however, by low concentrations of ethylenediamine tetra-acetic acid (versene), *o*-phenanthroline and α-α′-dipyridyl. Fifty per cent inhibition by versene is obtained with a final concentration of 2 × $10^{-5}$ *M*. Table 1 shows that the inhibitory effect of versene can be entirely reversed by equimolar or greater concentrations of Mn$^{++}$, and by an excess of Ca$^{++}$. A thirty-fold molar excess of Mg$^{++}$ is required to reverse the versene inhibition. Vesiculase action is depressed by low concentrations of Hg$^{++}$ and Fe$^{++}$, and by iodoacetamide. The inhibition by Hg$^{++}$ is reversed by cysteine, which does not itself affect vesiculase. Heating to 70° for ten minutes destroys this coagulating enzyme.

Table 1

| Versene (m*M*) | $CaCl_2$ (m*M*) | $MnCl_2$ (m*M*) | Change in optical density |
|---|---|---|---|
| | Experiment 1 (Rat) | | |
| 0 | 0 | 0 | 0·238 |
| 0·23 | 0 | 0 | 0·030 |
| 0 | 0·77 | 0 | 0·240 |
| 0 | 0 | 0·77 | 0·228 |

| 0·23 | 0 | 0·77 | 0·288 |
| | Experiment 2 (Guinea Pig) | | |
| 0 | 0 | 0 | 0·760 |
| 0·21 | 0 | 0 | 0·086 |
| 0 | 0 | 0·21 | 0·765 |
| 0 | 0 | 0·42 | 0·755 |
| 0 | 0 | 1·42 | 0·096 |
| 0·21 | 0 | 0·21 | 0·765 |
| 0·21 | 0 | 0·42 | 0·750 |
| 0·21 | 0 | 1·42 | 0·730 |
| 0 | 0·21 | 0 | 0·750 |
| 0 | 0·42 | 0 | 0·770 |
| 0 | 1·42 | 0 | 0·760 |
| 0·21 | 0·21 | 0 | 0·193 |
| 0·21 | 0·42 | 0 | 0·362 |
| 0·21 | 1·42 | 0 | 0·620 |

Experiments carried out at 30° in cuvettes of light path 0·8 cm. All tubes contained 50 *μM* tris-(hydroxymethyl)-aminomethane buffer pH 7·2. The following additions were made in experiments 1 and 2, respectively: seminal vesicle proteins, 25 mgm., 20 mgm.; sodium chloride, 124 *μM*, 93 *μM*; crude vesiculase, 0·61 mgm., 1·5 mgm. Total volumes and duration of experiment: Exp. 1, 1·8 ml., 27 min.; Exp. 2, 1·4 ml., 100 min.

The vesiculase present in saline extracts of guinea pig coagulating gland is precipitated by the addition of ammonium sulphate at 0° between 30 and 50 per cent saturation. If this fraction is dissolved in and dialysed against 0·15 *M* sodium chloride, it may be purified further by the addition of acetone at 0° to a final concentration of 30 per cent. This procedure affords a purification of approximately thirty-fold over the activity of crude extracts. Coagulation can be induced with as little as 10 μgm. per ml. of this purified protein. These treatments also separate vesiculase activity from that of an extremely active enzyme, present in crude coagulating gland extracts, which hydrolyses tosylarginine methyl ester. The latter enzyme, which appears to be similar to the human seminal enzyme hydrolysing benzoylarginine ethyl ester described by Lundquist[7], is precipitated from crude extracts by ammonium sulphate at 0° between 50 and 80 per cent saturation. This fraction will hydrolyse about 1,500 micromoles of tosylarginine methyl ester per mgm. of protein per hour at 37° and *p*H 7·4. A small amount of the tosylarginine methyl ester-hydrolysing enzyme contaminating vesiculase in the 30–50 per cent saturation ammonium sulphate fraction is removed by the subsequent treatment with acetone.

Sherry and Troll[8] have demonstrated that thrombin prepared from a number of species will hydrolyse tosylarginine methyl ester rapidly. Moreover, the action of thrombin upon fibrinogen is inhibited by tosylarginine methyl ester, apparently by a competitive mechanism. The fact that vesiculase can be separated from the tosylarginine methyl ester-hydrolysing enzyme in the coagulating gland, and that the action of vesiculase is not inhibited by tosylarginine methyl ester, suggests that vesiculase and thrombin are not identical. The dissimilarity between semen and blood coagulation is further borne out by the fact that at *p*H 7·4, bovine thrombin (15–36 units per ml.) will not coagulate the proteins of the seminal vesicles of rodents, and that guinea pig vesiculase does not coagulate either bovine or human fibrinogen (1 per cent) in the absence or presence of $Ca^{++}$.

It is a pleasure to acknowledge the advice and assistance of Dr. Dorothy Price in these investigations. This work was supported by grants from the American Cancer Society upon recommendation of the National Research Council Committee on Growth.

# FUNCTION OF CAROTENOIDS IN PHOTOSYNTHESIS

It is a rule without known exceptions that carotenoids accompany chlorophyll in the photosynthetic apparatus of all phototrophs from bacteria to higher plants[1]. Careful measurements of photosynthetic action spectra have shown that the light absorbed by carotenoids can be used for photosynthesis by some, but not by all, the organisms so far examined[2]. It seems, therefore, that direct participation of carotenoids as agents of energy transfer in the chain of primary photochemical events must be regarded as a well-established but by no means universal function of these pigments in photosynthetic organisms.

Some observations that we have recently made with the photosynthetic bacterium *Rhodopseudomonas spheroides* suggest a second, hitherto unsuspected function for carotenoids in photosynthesis, which could well explain the universality of their association with the photosynthetic apparatus: namely, protection of the cell from photodynamic destruction by chlorophyll, its principal light-absorbing pigment.

*Rhodopseudomonas spheroides* is a non-sulphur purple bacterium (family Athiorhodaceae). As shown diagrammatically in Fig. 1, the photosynthetic metabolism of non-sulphur purple bacteria differs from that of green plants. The oxidized moiety arising from the photochemical scission of water, which in green-plant photosynthesis is liberated as oxygen, serves in these bacteria as an oxidant for externally furnished hydrogen donors. Bacterial photosynthesis is thus an anaerobic process, which occurs in the light in the presence of suitable organic hydrogen donors. Many non-sulphur purple bac-

Via peroxides to $O_2$ (plants)
To oxidation of external organic H-donors (non-S purple bacteria)

Fig. 1. Primary reactions in photosynthesis

teria, including *R. spheroides*, can also be grown in the dark. Under such conditions they obtain the energy required for growth by the aerobic oxidation of the organic compounds that serve anaerobically as hydrogen donors for photosynthetic metabolism.

These bacteria also differ from most green plants in the structure of their photosynthetic apparatus. They lack chloroplasts; instead, the photosynthetic pigment system is contained in numerous submicroscopic particles termed chromatophores, each of which is some 50 mμ in diameter[3]. A similar intracellular organization of the pigment system is found in other photosynthetic bacteria[4] and in one plant group, the blue-green algae[5].

The photosynthetic pigments of purple bacteria are bacteriochlorophyll, which is identical throughout the group, and carotenoids, which differ from species to species[6]. *R. spheroides* contains a red and a yellow carotenoid, partly characterized some years ago by van Niel[7]. The colour of the cells varies from brown to red, depending on the conditions of cultivation. We have isolated three classes of mutants which differ from the wild type in their carotenoid constitution. Mutants of the *green* phenotype contain two new yellow carotenoids; those of the *brown* phenotype contain one of these new yellow carotenoids, together with the wild-type yellow and red carotenoids; and those of the *blue-green* phenotype contain no coloured carotenoids. Organisms of the green and brown phenotypes are physiologically normal, whereas those of the blue-green phenotype, although still capable of photosynthesis, display a number of striking biochemical and physiological aberrations, all of which appear to be ultimately referable to the absence of carotenoid pigments.

## Location of the Primary Genetic Block in the Blue-Green Mutant

Fig. 2 shows the spectra of the blue-green mutant and the wild type, both grown anaerobically in the light. The spectra were measured in a special cuvette holder with a pane of opal glass between the suspensions and the photocell, which minimizes the effects of light scattering[8]. The peaks at 375 mμ, at 590 mμ, and beyond 800 mμ indicate absorption by bacteriochlorophyll. In the spectrum of the wild type, the complex system of peaks between 440 and 570 mμ reflects the composite absorption by the two carotenoids. The spectrum of the blue-green mutant shows no peaks in this region; and the absence of coloured carotenoids was confirmed by column chromatography of extracts prepared from the cells. The bacteriochlorophyll in such extracts is spectrally identical with pure bacteriochlorophyll[9], and yields on acid treatment a spectrally typical bacteriophæophytin. When the effluents from columns were examined spectrophotometrically, they were found to contain large quantities of a colourless substance with the characteristic ultra-violet absorption spectrum of phytoene, a $C_{40}$ polyene that has been isolated from a variety of plant sources[10]. From the published values for the specific absorption of phytoene[10] and of the wild-type carotenoids[7], it could be calculated that the amount of phytoene in cells of the blue-green mutant is of the same order of magnitude on a weight basis as the amount of coloured carotenoids in the wild type. Most of the phytoene is localized in the chromatophores. In conformity with earlier observations[11], we were unable to detect phytoene in cells of the wild type.

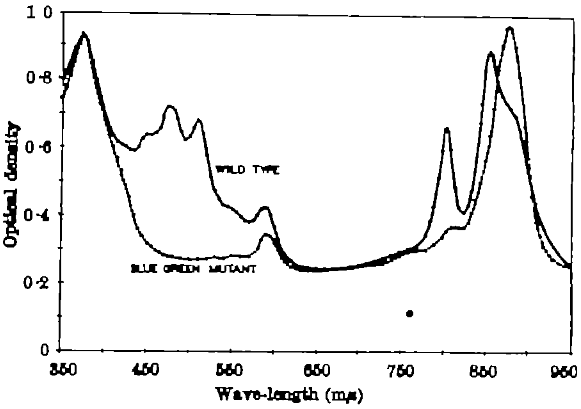

Fig. 2. Spectra of whole cells, adjusted to same densities at 680 mμ

Porter and Lincoln[12] have postulated that phytoene is one of the normal biosynthetic precursors of carotenoids. Although the role of the Porter–Lincoln series (phytoene, phytofluene, ζ-carotene, etc.) in normal carotenogenesis has been questioned[13], the probability that these compounds do have a biosynthetic function has been increased by recent findings with mutants of *Chlorella*[14], in which genetic blockage of normal carotenogenesis leads to an intracellular accumulation of one or more members of the Porter–Lincoln series. It therefore seems reasonable to formulate the primary biochemical lesion in blue-green mutants of *R. spheroides* as follows:

$$\cdots\cdots\rightarrow \text{phytoene} \Big| \xrightarrow{(n \text{ steps})} \text{coloured carotenoids}$$

Reversion of blue-green mutants, which is common in some strains, yields a phenotype indistinguishable from that of the wild type.

## Influence of Cartenoids on the Spectrum of Bacteriochlorophyll *in vivo*

The absence of peaks in the carotenoid region is not the only difference between the absorption spectrum of the blue-green mutant and that of the wild type. Despite the fact that the mutant contains normal bacteriochlorophyll, the infra-red spectrum of its cells shows very marked changes. The peaks at 805, 855 and about 880 mμ characteristic of the wild type (and also of the green and brown mutants) have given place in the blue-green mutant to a perfectly symmetrical main peak at 875 mμ with low shoulders at 760–780 and 800–825 mμ (Fig. 2). As a result of these changes, the general shape of the chlorophyll absorption spectrum in the cells of the blue-green mutant has come to resemble that of pure bacteriochlorophyll in organic solvents (Fig. 3), although the absolute positions of the main peaks still differ widely.

Complex infra-red spectra like that of wild-type *R. spheroides* are shown by most purple bacteria, although the number, position and relative heights of the peaks differ from species to species[15a]. The interpretation of these supernumerary peaks, which have no counterparts in the spectrum of bacteriochlorophyll *in vitro*, has been discussed by several authors[15], and it is generally concluded that they reflect the presence in the cell of several different chlorophyll-protein conjugates. However, the simpli-

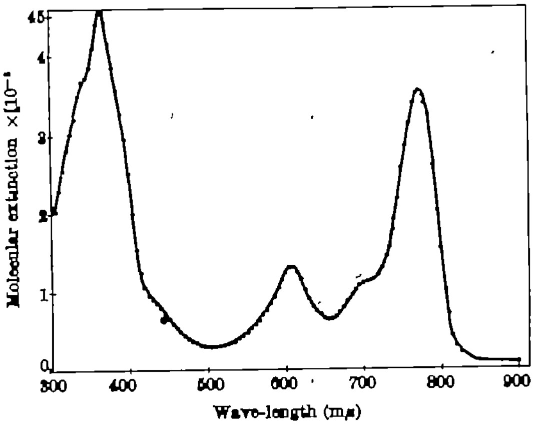

Fig. 3. Extinction curve for bacteriochlorophyll in methanol

fication of the infra-red spectrum that accompanies the disappearance of carotenoid pigments in the blue-green mutants points to a different interpretation. We suggest that the normal multi-peaked spectra are caused by a close and regular spacing of chlorophyll and carotenoid molecules in the photosynthetic unit, which is lost in the blue-green mutant when normal carotenoids are replaced by phytoene, a much more highly saturated compound lacking the molecular rigidity characteristic of the coloured carotenoids.

## Porphyrin Excretion

Media in which the blue-green mutant has been grown under photosynthetic conditions contain green, water-soluble pigments with a composite spectrum characteristic of porphyrins. The wild type can also excrete porphyrins during photosynthetic growth, but they are of a different nature (principally coproporphyrin III, according to Lascelles[16]). By solvent partition and chromatography we have separated the porphyrins excreted by the blue-green mutant into two major and two minor components. One of the minor components is bacteriophæophorbid. The other three substances are phorbids of the *a* series, spectrally very similar to one another and to phæophorbid *a*.

Porphyrin excretion by the blue-green mutant can be differentiated physiologically as well as chemically from porphyrin excretion by the wild type. In wild-type cultures, porphyrins are liberated into the medium only at the end of exponential growth, as the population is entering the stationary phase; in cultures of the blue-green mutant liberation of porphyrin parallels exponential growth, and diminishes with the onset of the stationary phase. The excretion of chlorophyll derivatives by the blue-green mutant is correlated with a subnormal chlorophyll content of the cells (Table 1).

These facts can be interpreted as follows. In the blue-green mutant, the geometry of the chromatophore is drastically changed by the absence of carotenoids, as evidenced by the changes of the infra-red spectrum. Furthermore, the sub-normal chlorophyll content of the cells indicates that less chlorophyll can be accommodated in the chromatophore than is possible for the wild type. However, since the primary genetic block in the blue-green mutant lies in synthesis of carotenoid, the synthesis of chlorophyll by the cell presumably proceeds at the normal rate, and as a consequence the unincorporated surplus must be disposed of in some fashion, the means adopted being excretion of chlorophyll derivatives into the medium. The phorbids which are excreted may be either intermediates in the normal biosynthesis of chlorophyll, or products of its intracellular enzymatic degradation. In any event, it is worthy of note that a photosynthetic bacterium can produce several derivatives of chlorophyll *a*, since the synthesis of this class of substances has been considered up to now the exclusive prerogative of plants[1] and organic chemists[17].

Table 1

| | | Growth conditions* | | | |
|---|---|---|---|---|---|
| | | Anaerobic, at light intensity of<br>270 foot-candles | 670 foot-candles | 1,800 foot-candles | Aerobic, dark |
| Growth-rate† | Blue-green | 0·051 | 0·17 | 0·20 | 0·31 |
| | Wild type | 0·175 | 0·24 | 0·31 | 0·31 |
| Chlorophyll content‡ | Blue-green | 1·1 | 0·86 | 0·47 | — |
| | Wild type | 1·6 | 0·89 | 0·51 | — |

* All experiments conducted at 30° C. in a medium containing: a vitamin–salts mixture; casein hydrolysate; and ammonium malate as principal hydrogen donor. Anaerobic cultures aerated with 95 per cent nitrogen – 5 per cent carbon dioxide; aerobic cultures with 95 per cent air – 5 per cent carbon dioxide.

† Expressed as the reciprocal of the generation time in hours.

‡ Measurements made on cells under steady-state conditions of pigment synthesis, and expressed as mgm. of chlorophyll per 100 ml. of culture with optical density of 1·000 at 680 mμ.

## Physiology of Growth of Bacteria

The relative growth-rates and chlorophyll contents of the blue-green mutant and of the wild type under a variety of environmental conditions are shown in Table 1. Under anaerobic conditions at any given light intensity, the mutant contains less chlorophyll and grows more slowly than the wild type; the divergences are particularly marked at low light

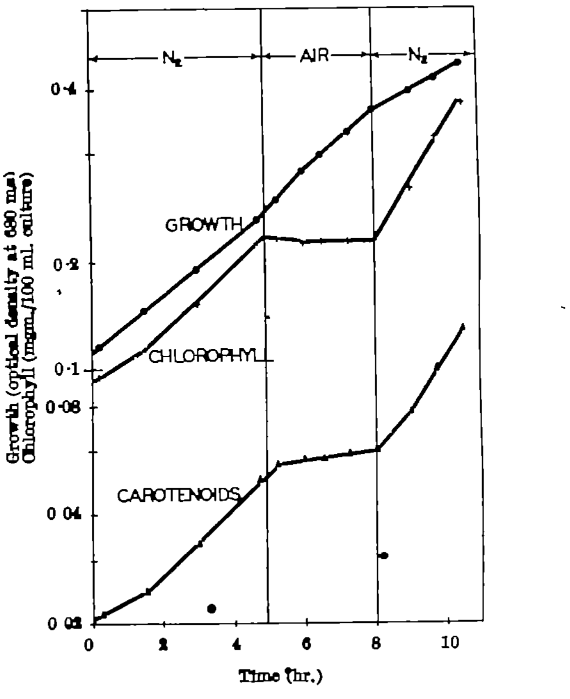

Fig. 4. Effect of air on growth and pigment synthesis by wild type of *R. spheroides*. Continuous illumination

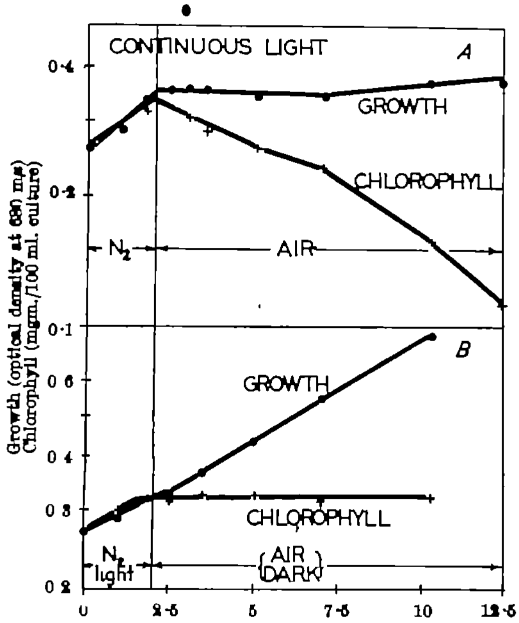

Fig. 5. Effect of air on growth and pigment synthesis by blue-green mutant of *R. spheroides*. *A*, continuous illumination; *B*, culture shielded from illumination just before introduction of air

intensities. Under aerobic conditions in the dark, the growth-rates are identical.

In studies on the kinetics of pigment synthesis by the wild type and the green mutant, we have found that, even in the presence of light, air almost totally inhibits both chlorophyll and carotenoid synthesis by growing cultures, but does not destroy the preformed intracellular pigments. When air is introduced into an illuminated culture previously growing under anaerobic conditions, the growth-rate is either unaffected or slightly increased; presumably photosynthesis continues for a certain period but is increasingly replaced by respiration as the pigment system of the cells is diluted by growth. A typical experiment with the wild type showing the effects of air is shown in Fig. 4. When a similar experiment was conducted with the blue-green mutant, the results were dramatically different (Fig. 5*A*): shortly after the introduction of air, growth ceased abruptly, and the preformed chlorophyll in the cells began to disappear. The arrest of growth indicated massive killing, as shown by viable counts. Death can be prevented by shielding the culture from light just before the introduction of air; under these conditions, growth continues, and the preformed chlorophyll in the cells is not destroyed (Fig. 5*B*). Since neither light nor air alone will kill the mutant, it is evident that death results from photodynamic action[18].

Two possible photosensitizing agents are present: the bacteriochlorophyll in the cells, and the excreted chlorophyll derivatives. Since the principal absorbing region of bacteriochlorophyll *in vivo* lies between 820 and 920 mμ, whereas none of the excreted compounds absorbs light at wave-lengths longer than 800 mμ, a simple experiment to decide between these possibilities suggested itself. The mutant was grown photosynthetically with infra-red light transmitted by a filter (Eastman 87*C*) completely opaque to all wave-lengths shorter than 800 mμ, and the effect of introducing air was determined. Under these conditions, air caused cessation of growth and destruction of chlorophyll in a fashion comparable to its effect on a control culture growing in white light. This experiment shows that the photosensitization of the blue-green mutant is attributable mainly, if not exclusively, to the intracellular bacteriochlorophyll. Since carotenoid-containing strains of the same organism do not show such a photosensitization, the conclusion that they are protected by their carotenoids seems inescapable.

If protection from photosensitization is a general carotenoid function, it follows that the carotenoidless condition should be compatible with photosynthetic growth only in bacteria, since these are the only phototrophs that can be grown in the light in the complete absence of oxygen. A green plant without carotenoids, even if initially placed in anaerobiosis, would presumably produce upon illumination the oxygen necessary for photodynamic death, and hence such a mutation in a plant should prove lethal under all conditions in the light. Claes[14] has recently described carotenoidless mutants of the green alga *Chlorella* that accumulate one or more members of the Porter–Lincoln series. These mutants can be grown only in the dark and are killed by exposure to light, a finding in agreement with the role for carotenoids that we postulate. Since it is well established that carotenoids can absorb light used in photosynthesis, protection from photodynamic death is evidently not their sole function in photosynthetic organisms; but we suggest that it may be the primary and most important one. On this view, the use of carotenoids as ancillary photosynthetic pigments by some organisms might be regarded as a later evolutionary adaptation.

In the preceding communication, some observations are described on the photosynthetic bacterium *Rhodopseudomonas spheroides* and some of its mutants, which indicate quite clearly that the presence of visibly coloured carotenoid within the cell prevents the killing of the cell when exposed simultaneously to oxygen and light, and that this killing is produced by light absorbed by the bacteriochlorophyll in the absence of coloured carotenoid. It may be associated with a similar phenomenon described for carotenoid-deficient mutants of *Chlorella*[1]. For the latter, however, the requirement of the presence of oxygen for the photokilling of the cell has not yet been demonstrated,[1] although it seems likely that it will be so.

The suggestion is made by Prof. Stanier and his colleagues that this 'protective action' of the carotenoid may represent a significant primary positive biological function of the carotenoid which had survival value and therefore, by implication, was and is a variable upon which evolutionary selection was based. When an attempt is made to formulate the molecular basis for this phenomenon (protection against photo-oxidative destruction), a somewhat different point of view regarding the reasons for its existence presents itself.

If one interprets the phenomenon in terms of an ability or function of the carotenoid to remove the 25–40 kcal. of excitation energy from the chlorophyll in some useful way prior to its use in the activation of some oxidation reaction by molecular oxygen, the protective action arises as an incidental result. Photosensitized oxidations by molecular oxygen and dyestuffs of the type of chlorophyll and of chlorophyll itself, in fact, are very well known. The photosensitized oxidation of thiourea by chlorophyll has indeed been used in actinometry, and the more general photosensitized oxidation of a large variety of unsaturated compounds by molecular oxygen has been studied in some detail.

The mechanism for this sensitized oxidation as formulated by Schenck[2] has been used by others[3] for accounting for a variety of photo-oxidations sensitized by porphyrins; it involves the transition of the first excited singlet state of the porphyrin into a long-lived (longer than $10^{-3}$ sec.) triplet state of the porphyrin[4]. This triplet state is then presumed to combine with the paramagnetic oxygen molecule to form a reactive peroxide[3]. The reactive peroxide can transfer its oxygen to a suitable reductant, leaving the sensitizer to return to its original ground-state. Such reductants have been substances such as ascaridol, etc.[1], and other oxidizable materials such as the thioctic acid disulphide[3a].

There is evidence that precisely such a process of absorption and transition to a long-lived (longer than $10^{-3}$ sec.) state by chlorophyll takes place in the plastids of photosynthetic organisms[5]. If the carotenoid were to play a part in the transport or transformation of the energy from this state, so that in the absence of carotenoids this state would have a greater probability of active peroxide formation in the presence of molecular oxygen, the phenomena above described would be expected to follow. Indeed, evidence for the likelihood of such a function for the carotenoid is also found in another observation described by Prof. Stanier and his colleagues. This is the great reduction, amounting to almost the disappearance, of the absorption bands at 8000 and 8550 A. from the mutant lacking coloured carotenoid, without any concomitant change in the porphyrin composition of the cell to which this might be attributed. As suggested by them, the disappearance of these absorption bands appears to be due to some change in the geometry of the plastids. More specifically, we would suggest that this absorption band is associated with the existence of a pi-complex between the carotenoid and the chlorophyll, models for which are to be found in the several systems which have been described by Scheibe[6] over the past twenty years. Such an interaction would indicate a close coupling between the electronic systems of the two molecules and provide a very effective pathway for energy transport or transformation. That such a transfer may take place in the reverse direction had been demonstrated by the observation of chlorophyll fluorescence induced by carotenoid light absorption[7].

From this point of view, the 'normal' function of the carotenoid would be in one of the following steps: (1) in the conversion of the long-lived electronic chlorophyll excitation into reducing and oxidizing agents (electrons and holes; it is not unlikely that the extra absorption bands mentioned in the previous paragraph are charge-transfer spectra related to this process)[5b,c]; (2) in the succeeding separation of these agents by a process of conduction in the conjugate chain; or (3) as a coenzyme in the conversion of the oxidant initially formed (to oxygen in the green plant or to oxidize the hydrogen donor in the photosynthetic bacteria). In performing any of these energetically useful functions it would, of course, inhibit the photosensitized oxidation of such essential sensitive cell constituents as disulphides and mercaptans. An apparently alternative mechanism for the 'protection' would be for the carotenoid to act as 'most-favoured' oxygen acceptor from the reactive peroxide. This would require a reductive process for the regeneration of carotenoid, and it might even be a process yielding energy, in which case it would correspond to the third possibility mentioned above.

Since all these functions would be considered essential steps in the ability of a cell to use light energy for growth, it is necessary to recognize the requirement for something able to perform these functions, although perhaps less efficiently, in the case of the anaerobic photosynthetic growth of the blue-green mutant. This may be the less conjugated phytoene, or some other as yet unrecognized cell constituent.

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Radiation Sensitivity of Ovarian Tissue at −79° C.

Gonadal tissue of rats, soaked *in vitro* in media containing glycerol, can be subjected to very low temperatures without losing its capacity to form an endocrinologically active graft[1]. This observation has made possible the extension to normal tissues of work on the temperature relations of radiation effects which has hitherto been restricted to small ranges of temperatures, or, so far as mammalian material is concerned, to certain tumour cells[2].

Rat ovarian tissue was chosen for the experiments because of the wealth of information about its behaviour *in vitro* and on grafting, and because, in addition to the endocrine cells, the ova offer a highly sensitive indicator of irradiation effects. So far as I am aware, no experiments on X-irradiation *in vitro* have been carried out with ovarian tissue even at normal temperatures, though this method has been used with adrenal grafts[3]. *In vivo*, however, exposure of the rat ovary to 500–3,000 r. causes destruction of the ova[4]. Direct destruction of the endocrine tissue of the ovary must be distinguished from the curtailment of its functional life which may follow destruction of the ova[5].

There are three main indices of the endocrine effectiveness of ovarian grafts in ovariectomized females: the proportion of animals in which the grafts 'take', the latent interval before they become functional and the survival-time of the graft as a functional organ. In rats, the restoration and maintenance of the vaginal cycle in ovariectomized recipients, readily effected by the transplantation of normal ovarian tissue, is a convenient indication of functional activity of the graft. In this communication, 'activity' refers only to endocrine activity thus determined, there being no question of fertility with subcutaneous grafts.

In most of the experiments to be considered here, the two ovaries were removed early in the morning, cut into eight quarters, soaked in 15 per cent glycerol-saline or glycerol-serum for one hour, and sealed in glass ampoules. The ampoules were then immersed in alcohol at room temperature (controls), or frozen in the slow cooler previously described[6] and immersed in alcohol maintained at −79° C. by solid carbon dioxide in a vacuum jar. The jars were dispatched immediately to the Experimental Radiopathology Research Unit at Hammersmith, where the ampoules, still immersed in alcohol, were irradiated under conditions which ensured that a known dose was received by the ovarian tissue contained in the ampoules. The jars were then brought back to Mill Hill, and the tissue transplanted subcutaneously to the donors.

With two sets of operations and slow freezing to be carried out on the same day, the necessity for transporting the material across London for irradiation placed a severe restriction on the design of the experiments. At first, control material was put simultaneously through the same procedure, without irradiation; but with four types of treatment going on simultaneously the number of animals in each category was so reduced that in later experiments the non-irradiated control grafts were made on the previous day. Also, attempts to relieve the logistic difficulties by using material frozen for more than a few hours were complicated by the greater freezing damage thus incurred.

Irradiation was from a Philips 'Metallix' X-ray tube run at 190 kV. and 6 m.amp., giving a dose-rate to the tissue of 68 r. per min. Three levels of dosage were used at room temperature on material in glycerol-saline: 1,000 r., 3,300 r. and 6,600 r. Tissue which had received 1,000 r. established itself as a graft and, over a short period of observation, functioned normally and, at least for a time, contained normal ova. At the other extreme, no functional grafts were obtained from material irradiated with 6,600 r. The intermediate dose did not prevent entirely the establishment of endocrinologically functional grafts; but it greatly decreased their effectiveness and no ova were found in such grafts. Attention was therefore concentrated on irradiation with 3,300 r., and various sighting experiments at room temperature and at −79° C. showed that the effect was influenced by the nature of the medium and by the amount of damage attributable to freezing alone. A four-point experiment based on the results of the preliminary work, in which 15 per cent glycerol-serum was used because of the added protection it gives to ovarian tissue against freezing damage[7], yielded the results summarized in Table 1.

Table 1. Effect of Temperature on Irradiation Damage to Rat Ovarian Tissue

Two replications of a 4-point experiment, 40 rats in all

| *In vitro* treatment of tissue before grafting | | Effectiveness of graft | | |
|---|---|---|---|---|
| | | Proportion of 'takes' | Average latent interval (days) | Proportion active at seven weeks |
| Not irradiated | Soaked only at room temperature | 10/10 | 7·8 | 10/10 |
| | Frozen to − 79° C. | 10/10 | 12·8 | 10/10 |
| Irradiated (3,300 r.) | At room temperature | 2/10 | 21·0 | 0/10 |
| | At − 79° C. | 9/10 | 20·5 | 5/10 |

The following conclusions may be drawn.

(*a*) The grafting of ovarian tissue which had been soaked in glycerol-serum but neither frozen nor irradiated produced effects similar to those previously reported.

(*b*) Freezing alone increased the latent interval, but did not affect the proportion of 'takes' or, within the period of observation, the functional survival-time of the graft.

(*c*) Irradiation with 3,300 r. at room temperature greatly reduced the number of 'takes', increased the latent interval by nearly three times and shortened the functional life of the graft.

(*d*) Irradiation at − 79° C. was less damaging because both the proportion of 'takes' and the survival-time of the graft were much increased as compared with irradiation at room temperature, in spite of some additional damage due to freezing.

Histological examination of the material discussed in the table showed that there was little difference between the two types of non-irradiated grafts; both frozen and fresh tissue gave rise to active-looking grafts with abundant ova, follicles and corpora lutea. Where the tissue had been irradiated at room temperature, only degenerate bits could be recovered at autopsy and these consisted histologically of small nests of old luteal cells. The grafts obtained from tissue irradiated at − 79° C. also consisted mainly of luteal tissue, but much of this was in the form of old but still well-organized corpora lutea. Ova were not seen, and there is no suggestion that under the conditions of this experiment low temperature gave any significant protection to the eggs against the excessive dose of X-rays employed.

The results must be regarded as preliminary, and evidently a host of variables remain to be investigated in connexion with even this one type of tissue. Nevertheless, the experiments justify the conclusion that under certain conditions a temperature of − 79° C. appears to afford some protection to rat ovarian tissue against irradiation effects.

I am much indebted to Dr. G. Popják, who arranged for the irradiations at the Experimental Radiopathology Research Unit, and my especial thanks are due to Dr. M. Ebert, who carried out the irradiations and whose study of dosimetry under unusual conditions was vital to the work recorded. The operative procedures were carried out by Miss M. Moylan.

# Identification of N$^2$-Methylguanine (2-Methylamino-6-hydroxypurine) as a Normal Constituent of Human Urine

A recently initiated re-investigation[1] of the free purine bases (other than methylxanthines of dietary origin or uric acid) normally occurring in human urine showed that in addition to xanthine, hypoxanthine, adenine and 7-methylguanine, isolated in older work[2], guanine, 1-methylguanine, and a number of as yet unidentified substances of purine-like properties were present. The procedure used segregation of amphoteric components by absorption on 'Dowex 50' resin and elution with ammonia, precipitation of the purines with acid silver nitrate, two-dimensional paper chromatography of this concentrate, elution and ultra-violet spectrophotometry. Improved ultra-violet illumination has revealed the presence of an additional substance the ultra-violet spectrum of which strongly suggests a substituted guanine structure; this appears as a faint spot on the paper chromatograms, between 'spot $U$'[1] and adenine.

A small specimen of this unknown substance was isolated by ion exchange chromatography[3] and further purified by paper chromatography. Its mobilities on paper chromatograms in four solvents (Table 1) and its spectra at five $pH$ values (Fig. 1) were found to be in excellent agreement with those of a synthetic specimen of N$^2$-methylguanine[4].

* 0·07 $M$ phosphate buffer.
† 0·05 $M$ borate buffer.

Analogous to the case of N$^6$-methyladenine and of 8-methylaminopurine[5] was a small shift to longer wave-length of the absorption maxima of N$^2$-methylguanine relative to those of guanine. To confirm further the identity of the unknown with synthetic N$^2$-methylguanine, both were treated with nitrous acid. (To a suspension of 0·25 mgm. of substance in 0·25 ml. of 2 $M$ acetic acid at 60°, 0·05 ml. of 1 $M$ sodium nitrite was added over a 10-min. interval.) The paper mobilities and ultra-violet absorption of the product from either specimen again coincided within experimental error (Table 1). The structure of the product is at present unknown. The substance produced by action of nitrous acid on N$^6$-methyladenine has been tentatively formulated as an N$^6$-nitroso derivative[6].

The urine of all the normal human subjects examined contained the new compound. The average daily urinary excretion was 0·5 mgm. The urinary excretion of N$^2$-methylguanine, and of the purines earlier described[1], was not significantly changed after three days on a diet restricted to glucose and water,

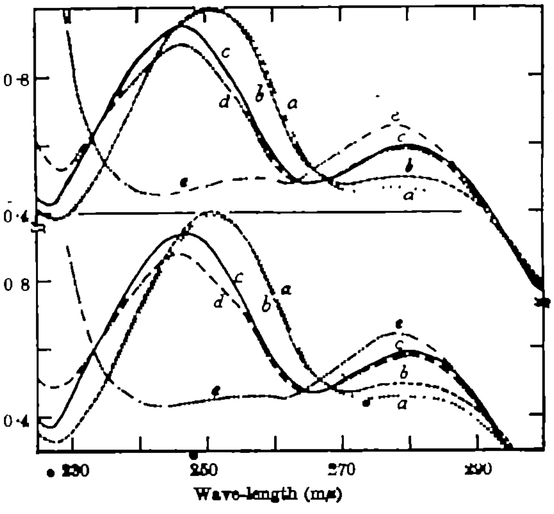

Fig. 1. Ultra-violet spectra of the urine isolate (lower curves) and synthetic N$^2$-methylguanine (upper curves). (a) in 1 $M$ hydrochloric acid · · · · · ·; (b) at $p$H 2·1, – – – –; (c) at $p$H 6·2, ———; (d) at $p$H 9·0, ———; and (e) in 1 $M$ sodium hydroxide, — — · —

or after sterilization of the intestinal tract by ingestion of neomycin and succinylsulphathiazole. This indicates that they are products of endogenous metabolism in man, and not dietary or bacterial in origin.

This identification of N$^2$-methylguanine as a urinary constituent seems to be the first time it has been recorded in a natural product. Of interest in this connexion is the recent demonstration of N$^6$-methyladenine[6] and of N$^6$-dimethyladenine[7] in bacterial and fungal sources. With the earlier identification of 7-methylguanine[2] and 1-methylguanine[1], the identification of N$^2$-methylguanine brings the number of methylated guanines in human urine to three. A possible fourth such derivative is the substance designated[1] 'spot *K*', which is still under investigation. The similarity of the spectra of this substance to those of 8-hydroxyguanine at a number of *p*H values and other evidence suggest that it may be a methylated 8-hydroxyguanine. The possibility that methylated guanine derivatives may play some significant part, as yet unexplored, in human metabolic processes is indicated.

We wish to thank Dr. Gertrude B. Elion, of the Wellcome Research Laboratories, for making available a specimen of synthetic N$^2$-methylguanine. The investigation was supported in part by a grant-in-aid from the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health.

## Normal Blood Picture of the Guinea Pig

In the course of general research into the effect of various drugs on the hæmopoietic system of the guinea pig, it was necessary to observe and record the normal blood picture, since there is considerable variation in the results given by other workers[1,2]. These records of the normal were primarily obtained to provide a base-line for combined investigations on the reticulo-endothelial system and the blood in relation to the defence mechanism of the body.

The results we have obtained are from 53 intact male guinea pigs which varied in weight from 300 to 570 gm. The blood was removed from a marginal vein of the ear and also from the heart.

*Erythrocytes.* The average total count was found to be 5 million per c.mm. with a variation up to 0·4 million cells. Other workers[3] record a range of 3·7–7·7 million, but the majority are in agreement with a total of about 5 million. In comparison with human blood, there is a slight degree of poikilocytosis, anisocytosis and polychromasia.

*Hæmoglobin.* The hæmoglobin-level was determined by the Sahli method and averaged 81 per cent. Others[3] give values of 75–110 per cent.

*Platelets.* The average number in the present series of animals was 71,000 per c.mm., but varied from 54,000 to 100,000.

*Leucocytes.* The average total count was found to be 9,100 per c.mm. This varied between 5,000 and 15,000; but most of the animals showed a count of between eight and ten thousand.

DIFFERENTIAL COUNT

| | Average (per cent) | Range (per cent) |
|---|---|---|
| Lymphocytes | 64 | 55–81 |
| Pseudoeosinophil granulocytes | 32 | 16–44 |
| Immature granulocytes | 0·1 | 0–1 |
| Eosinophil granulocytes | 0·6 | 0–3 |
| Basophil granulocytes | 0·2 | 0–2 |
| Monocytes | 3·1 | 0–7 |

The normal blood picture is therefore one of 'lymphocytosis'. The pseudoeosinophils are the counterpart of the neutrophils of human blood. Compared with the true eosinophils, they show finer granules in their cytoplasm, do not exhibit certain specific staining (Zollikofer's)[3] and show multiple segmentation of the nucleus, which usually has from four to seven lobes.

The Foa–Kurloff cells[4] in this series of male animals never exceeded 1 per cent of the leucocyte count and were only observed in some of the films examined.

There was no evidence that albino guinea pigs possess more circulating leucocytes than the coloured varieties.

The heart blood compared with that taken from the ear showed a slightly higher percentage of lymphocytes (72 per cent) and a small reduction in pseudoeosinophils (25 per cent), although the total leucocyte count showed no change.

The blood films were stained with Giemsa's stain and the platelet count estimated by comparison with the number of erythrocytes.

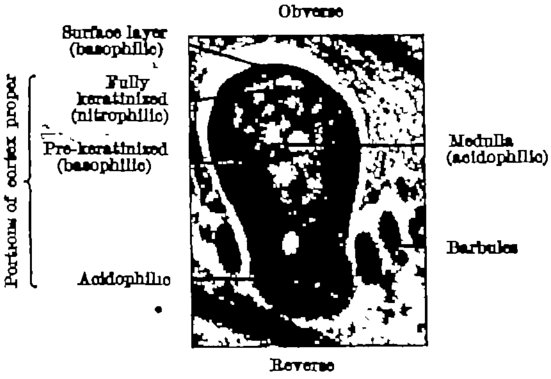
## Cortex and Medulla of Bird-Feathers

In fully developed mammalian fibres, the cortex shows an affinity for 'nitro' dyes, while the medulla retains any acid stain[1], this being clearly seen in Wildman's[2] colour photograph. Histogenetically, the affinity of the fibre medulla for acid dyes may be connected with its re-absorption or adsorption of the earlier segregated droplets of the intensely acidophilic trichohyalin[1], and it may also bear out the chemical specificity of the medulla, as compared with the cortex, pointed out by, for example, Bekker and King[3]. In contrast to its high and general affinity for 'nitro' dyes, the cortex of fully keratinized fibres shows a slight, regional affinity for basic stain[4]. However,



Obverse
Surface layer (basophilic)
Portions of cortex proper
Fully keratinized (nitrophilic)
Pre-keratinized (basophilic)
Acidophilic
Medulla (acidophilic)
Barbules
Reverse

Fig. 1. Part of a transverse section through a feather germ from a guinea fowl, showing a barb, in which the obverse portion of the cortex has attained full keratinization. × 500

before attaining keratinization within the follicle, the cortex shows a 'pre-keratinization' zone in which its previous, acidophilic state abruptly changes into an extremely intense affinity for basic stain[5,1].

Change from an acido- into an intensely basophilic state can be observed during differentiation of cortex also in bird feathers; but Auber's[1] staining procedure reveals that, with full keratinization, the cortex shows a greater and more general tendency to retain basic stain than does fibre cortex; this may be in conjunction with chemical differences between this layer in birds and mammals, found by earlier authors. As in mammalian fibres, the medulla of feathers shows an intensely acidophilic state, which persists after full keratinization; however, no droplets comparable to trichohyalin appear in the medulla at any stage.

Earlier work shows that differentiation and keratinization of the feather takes place in waves passing across the width of the rhachis and the barbs in a direction from the obverse to the reverse. Germs, particularly of large feathers, may show, in a corresponding arrangement, three phases of differentiation of the cortex, namely, full keratinization ('nitro'- or basophilic), pre-keratinization (intensely basophilic), and the early, acidophilic state, in one and the same cross-section of a barb (Fig. 1).

Sections through fully developed feathers may be stained successively with a basic and an acid stain (for example, basic fuchsin and picro-indigocarmine, or toluidine blue and acid fuchsin). After the initially applied basic dye has been extracted from the medulla with 70 per cent alcohol, this layer is stained by a short exposure to the acid dye. In conjunction with the ob–reverse progress of keratinization, reverse portions of the cortex may appear less intensely stained with the basic dye than the rest of the cortex, or they may attain a stain resulting from both dyes; however, they stand out clearly from the intensely acidophilic medulla. Such regional differences within the feather cortex may correspond histogenetically to the regional heterogeneity of the fibre cortex[6,4]. According to the type of bird, the obverse portion of the surface layer[7] may stand out from the cortex proper by an extreme intensity of the basic stain; or this portion may stain less intensely or even, when picro-indigocarmine is used for staining the medulla, it may stain with the 'nitro' dye (picric acid).

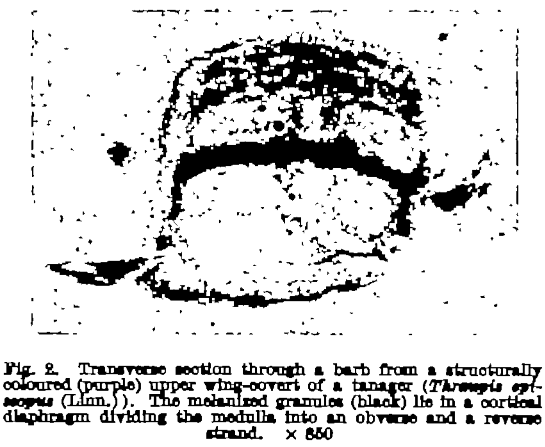


Fig. 2. Transverse section through a barb from a structurally coloured (purple) upper wing-covert of a tanager (*Thraupis episcopus* (Linn.)). The melanized granules (black) lie in a cortical diaphragm dividing the medulla into an obverse and a reverse strand. × 850

By applying such a differential stain, misconceptions by earlier authors[8] about the structure of some feathers can be rectified. Thus it can be shown that in barbs of, for example, some kingfishers and some tanagers, the light-absorbing melanins (necessary for production of Tyndall's blue) are situated, not in the medulla but in a cortical diaphragm which divides the medulla into two strands (Fig. 2). Moreover, in some kingfishers the melanins were found to lie in an isolated axial strand of cortical tissue, completely surrounded by a tube-shaped medulla (Fig. 3). A detailed account of the morphology of such atypically textured feathers is now being prepared.

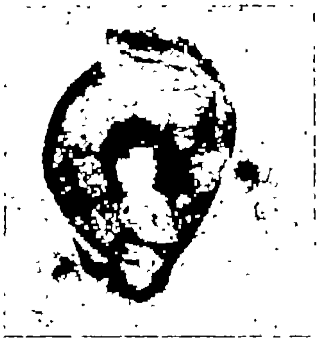

Fig. 3. Transverse section through a barb from a structurally coloured (purple) feather from the rump of a kingfisher (*Halcyon coromanda* (Lath.)). The melanized granules lie in an axial strand of cortical tissue which is completely enclosed by medullary cells. × 900

I am indebted to the Council of the Wool Industries Research Association for permission to publish these observations, and to Mr. H. M. Appleyard, Miss M. E. A. Perkin and Miss D. Davenport for preparing the photomicrographs.

## Factors Influencing the Motility of a Strain of *Pseudomonas viscosa*

The observation that *Pseudomonas viscosa* is motile only around bubbles of air when examined under a coverslip has led to the investigation of the effect of oxygen and other factors on its motility.

Distilled water suspensions of the organism (approximately 2,500 million viable organisms per ml.) from nutrient agar cultures were gently mixed and then drawn into flat capillary tubes made by a modification of the method of Wright and Colebrook[1]. The tubes were sealed, leaving an air space at one end, and examined microscopically.

Immediately after introduction into the capillary, the organisms were briskly motile throughout the length of the column of suspension; but after several minutes (average 7–10 min.) motility ceased except in a zone approximately 2–4 mm. in length next to the air, and was optimal in a narrow band 1 mm. or more from the air surface. The time required for general motility to cease could be increased to 80 min. by prolonged aeration of the suspension. The organism remained motile for periods up to several days at room temperature in the zone near the air, the duration of motility depending on the size of the air space. If, when all motility had finally ceased, the capillary tube was re-opened, motility re-commenced at the air-suspension interface immediately.

All the phenomena observed with air could be reproduced with oxygen; but motility was not maintained by hydrogen, nitrogen or carbon dioxide.

The use of fresh 50 per cent broth as the suspending medium gave different results. Motility in the centre of the column ceased at approximately the same time as that in the water control; but, after a pause of a second or two, the cells in the presence of broth began to move again, and remained motile for approximately two hours. This finding suggested a second factor promoting motility under relatively anaerobic conditions. Other reagents were tested for ability to give prolonged motility, and the results obtained are summarized in Table 1. They show that arginine was capable of producing all the phenomena noticed with broth, that the duration of motility increased with increasing concentrations of arginine, and that arginine was highly specific.

The temporary brief cessation of motility described above suggested that arginine was not utilized for motility until the available oxygen in the suspending medium had been reduced below a critical level. Experiments designed to test this point were made by comparing the duration of motility of suspensions aerated in the presence and absence of arginine with that of unaerated controls. The results showed that arginine was, in fact, utilized in aerated mixtures, but considerably more slowly than under conditions in which motility dependent upon oxygen had ceased.

To summarize: the motility of this strain may be activated either by a certain minimal concentration of molecular oxygen, or by arginine in the absence of sufficient available oxygen to allow the first mechanism to operate. These observations promise to throw further light on the biochemical processes controlling flagellar activity, and work is continuing in an attempt to determine the role and fate of arginine.

Table 1. Results of Mixing Equal Volumes of Aqueous Suspensions of *Ps. viscosa* and Some Different Reagents

| Reagents | Prolongation of motility beyond that of the water control. (Readings taken at more than 20 mm. from the air space) |
|---|---|
| Nutrient broth. Digest broth. Boiled broth. 0·1 per cent Thioglycollate broth. Brewer's medium. 1 per cent Peptone. L-arginine 1·2 m*M* | > 40 min. |

## Chloride Ions in the Secretion of the Pitcher Plant

Analogies between the pitchers of insectivorous plants of the genus *Nepenthes* and the mammalian stomach were first given biochemical justification when De Zeeuw[1] demonstrated that the proteolytic activity, long known to occur in the viscous secretion of opened pitchers, was also present in the juice of pitchers opened under sterile conditions and could hence not be of bacterial origin. A recent study of the secretions from opened and unopened pitchers of some fifteen species of *Nepenthes*, made available to me by courtesy of the Director of the Royal Botanic Gardens at Kew, makes it possible to suggest a yet closer analogy between the animal and vegetable organs.

It was found that, whereas the *p*H of the secretion in unopened and sterile pitchers fell within the range 4·2–6·6 (mean 5·5), it was some 2 *p*H units lower (2·3–4·6, mean 3·3) in the juice of freshly opened pitchers which, though not sterile, had not yet acquired a chemically important bacterial population. Chromatography on paper of the secretions of freshly opened pitchers showed no significant amounts of the commonly occurring organic acids. Tests with silver nitrate, however, showed chloride ions to be present in the juices of all pitchers. Whereas chloride was usually present in very low concentration in the immature organs, estimations by an iodometric method on the secretions of newly opened pitchers showed chloride ion concentrations in the range 600–900 mgm. per litre.

Although data are not yet available for the construction of an ion balance sheet, there seems to be a definite qualitative correlation between the hydrogen and chloride ion concentrations in the pitcher secretion of *Nepenthes*. Since, in general agreement with the results of earlier authors[2], the pitcher protease has been consistently found to show an optimum activity on hæmoglobin in the region *p*H 2–3, the provisional conclusion appears to be justified that the proteolytic action in the pitcher is established, as in the mammalian stomach, by concomitant secretions of a protease and of hydrogen ions, the latter being balanced by a simultaneous secretion of chloride.

It is interesting to note that chloride was first detected in the pitcher secretion by Voelker[3] in 1849.

I wish to thank Drs. L. Bentley and D. F. Cheesman for their advice in this investigation.

## A Crystalline Component of Carp Myogen precipitating at High Ionic Strength

Fractionation of carp myogen with ammonium sulphate reveals the occurrence of a component precipitating at neutral *p*H between 90 and 100 per cent saturation of ammonium sulphate. We have succeeded in isolating this constituent by the following method.

Fresh muscles are minced and extracted with water for 1 hr. at 2° C. The supernatant separated by centrifugation is dialysed in the cold against water. The globulins precipitated are discarded. The solution is brought to 88 per cent saturation by addition of solid ammonium sulphate and the *p*H is adjusted to 6·5. After elimination of the precipitate, solid ammonium sulphate is added to 98 per cent saturation. The solution is gently stirred for 1 hr. in the cold; the precipitate is separated by centrifugation and dissolved in a small amount of water. This solution, which gives rise to an important crystallization within 24 hr. at 2° C. (Fig. 1), has been examined by electrophoresis, ultracentrifugation and spectrophotometry, after dialysis against a phosphate – sodium chloride buffer of $I = 0·15$ and *p*H 7·3 ($I = 0·1$ phosphate + 0·05 sodium chloride).

Two electrophoretic gradients of closely similar mobilities are observed on the ascending side corresponding to the main gradient of carp albumins described by Hamoir[1,2] which migrate at $-3 \times 10^{-5}$ (ascending) and $-2·5 \times 10^{-5}$ (descending) cm.$^2$ volt$^{-1}$ sec.$^{-1}$ (same buffer as above). In the ultracentrifuge, a single peak is obtained with a corrected rate of sedimentation of about 1·5 *S*.

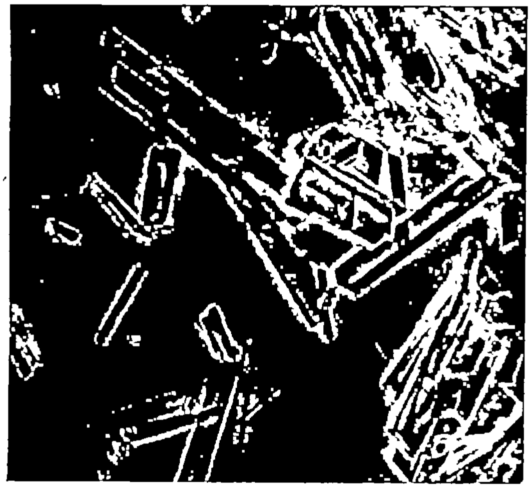

Fig. 1. Photomicrograph with phase-contrast microscope. × 350

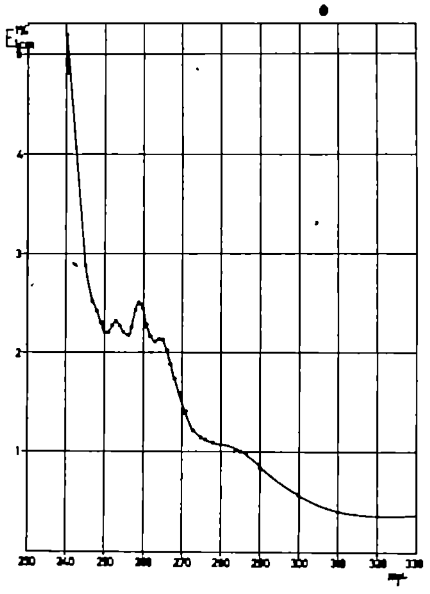

Fig. 2. Ultra-violet spectrum at *p*H 7·3. Ordinate, optical density of a 1 per cent solution; abscissa, wave-length in mμ

The ultra-violet absorption spectrum is shown in Fig. 2. It differs surprisingly from that usually observed with proteins. The absorption at 280 mμ is very low, and three peaks are observed at about 253, 259 and 264 mμ, identical to those described by Fromageot and Schnek[3] in the case of phenylalanine at neutral *p*H. This protein appears, therefore, to contain very little tyrosine and tryptophan, and a much higher proportion of phenylalanine. No protein, except gelatin, seems to have been described so far having such an unbalanced composition in cyclic amino-acids[4].

The occurrence in carp muscle albumins of a protein fraction having such electrophoretic and ultracentrifugal properties has already been inferred from the study of whole extracts[2]; but except myoglobin[6], no component had been isolated and crystallized hitherto from these low-molecular weight proteins, which appear to occur only in muscles of cold-blooded vertebrates[2,5].

## The 'Blow' of Whales

In a communication in *Nature* of June 25, 1955[1], attention was directed to the occurrence of an extremely stable foam in the lung passages of the rabbit. The foam was formed from a mucus composed of an insoluble protein, the surface tension of which was extremely low.

Foam with comparable qualities has been established as occurring naturally in the sinus system of the middle ear and in the trachea of whales (common rorqual, pilot whale and sperm whale). In these animals the foam is developed from a very finely divided emulsion of fat droplets in mucus, and gas. When it is spread out on a glass plate, the foam persists for several days and eventually dries to a meringue-like consistency.

In the region of the ear, the foam subserves a sound-insulating function[2]; but its occurrence in the respiratory passages suggests that it may also have the role of absorbing the residual nitrogen of the inspired air, both in the lungs and middle-ear sinuses. It is well known that fat has a nitrogen-absorptive capacity six times greater than that of blood[3]. In a foamed emulsoid form, the conditions for absorption are ideal.

This leads to consideration of the constitution of the 'blow' of whales, which has been the subject of much conjecture and not a little controversy. It has variously been thought to be formed of water, of condensed water vapour or of these combined with the exhaled breath. It is obvious that the lungs are not filled with water, and the amount thrown up by the exhaling whale while breaking surface does not seem adequate to account for the conspicuous and, to whaling men particularly, the specifically recognizable fountain which has so often been observed. The fact that the 'blow' is of equal visibility whether seen in the tropics or in colder latitudes would seem to rule out the condensed water-vapour hypothesis. It is suggested, therefore, that it is the nitrogen-charged foam which is expelled on exhalation.

A distinctive colour injection of the oil sinus of the 'melon' of a pilot whale was carried out at the Museum. The result points to a connexion between this supra-maxillary oil sinus and the mucous membrane of the middle ear air sinus. A similar connexion could be anticipated for the similarly situated spermaceti organ of the sperm whale. These liquid oil systems have no capillary vascular system in their interior, and the oil is therefore unlikely to be saturated with nitrogen at atmospheric pressure if the rate of oil synthesis exceeds that of nitrogen saturation. If the oil–nitrogen absorption idea is correct, it would be expected that an animal of the size and deep-diving capacity of the sperm whale would require a very considerable reservoir, such as the spermaceti organ, of liquid oil for emulsification. to replenish that lost at each exhalation.

## Interlamellar Sorption Complexes of Graphitic Acid with Organic Substances

GRAPHITIC acid has long been known[1] to show reversible interlamellar swelling with water[2], of the same apparent type as that shown by the clay mineral montmorillonite. As in the case of this mineral, reactions with organic substances of polar nature are to be expected; these, although mentioned in an early paper[3], appear not to have been systematically investigated using X-ray diffraction methods. This we are in process of doing.

Table 1. BASAL SPACINGS OF GRAPHITIC ACID COMPLEXES WITH ORGANIC SUBSTANCES

| Substance | Technique | *d*(001) | Δ |
|---|---|---|---|
| Dried over conc. sulphuric acid | *p* | 7·0 | — |
| Water in excess | *f* | 10·9 | 3·9 |
| Ethylene glycol | *p* | 9·6 | 2·6 |
| Glycerol | *p*, *f* | 10·0 | 3·0 |
|  | *o* | 9·2 | 2·2 |
| Acetone | *f* | 9·0 | 2·0 |
| Phenol in aq. sol. | *f* | 10·5 | 3·5 |
| Acrylic nitrile | *p*, *f* | 8·0 | 1·0 |
| Propionic acid | *f* | 9·2 | 2·2 |
| Amyl nitrite | *p* | 7·5 | — |
| Nitrobenzene | *p* | 8·8 | 1·8 |
| *m*-Nitroaniline in aq. sol. | *f* | 11·0 | 4·0 |
| Hexane + pentane | *f* | 7·6 | — |
| Carbon disulphide | *f* | 7·7 | — |
| Benzene | *f* | 7·3 | — |
| Ethylamine | *p* | 8·7 | 1·7 |
| *iso*Butylamine | *p* | 16·8 | 9·8 |
| Aniline | *p* | 18·5 | 11·5 |
| Aniline in aq. suspension | *p* | 23·1 | 16·1 |
| Naphthylamine in aq. sol. | *p* | 14·6 | 7·6 |
| Pyridine | *p* | 11·1 | 4·1 |

For the symbols used to indicate technique, see text. The sign — means no appreciable swelling. For measurements on alcohols, see Fig. 1.

Complexes can be formed simply by moistening the graphitic acid (previously dried) with the organic liquid, or with a suitable solution. Table 1 lists a few of the basal spacings we have observed in this way. In most cases they are derived from X-ray powder photographs, made with the graphitic acid powder in a Lindemann glass tube (indicated by *p* in Table 1); some from similar photographs of small oriented aggregates, as used in studying clay minerals[3] (*o*); others with a special flat-plate semi-focusing camera calibrated with mica (*f*).

The graphitic acid was prepared by treating powdered graphite with a mixture of potassium chloride, nitric and sulphuric acids[4]. It was not an entirely uniform product, the X-ray diagrams showing some unchanged graphite (002) spacing, which, however, caused no confusion. For some of the photographs, the most altered product was separated by sedimentation. The product, after drying over concentrated sulphuric acid, had a basal spacing of 7·0 A. It was perhaps still slightly expanded at this stage, or else some sulphate groups were present in interlamellar positions. The column headed Δ in Table 1 gives the expansion, with reference to an 'unexpanded' spacing of 7·0 A.

The observations referring to the aliphatic alcohols are of particular interest, and are shown graphically in Fig. 1. For the first three members the expansion is small, about 2·5 A., of the same order as that for glycol, glycerol and acetone. The next two alcohols give the same expansion together with a proportion (small for butanol, large for pentanol) of a much larger one. This large expansion increases from butanol to pentanol by an amount equal to the projected length of two C—C bonds, assuming an 'upright' orientation of the molecules as a whole on the graphite layers. Benzyl alcohol fits on the same slope, if it is given its 'effective' number of aliphatic straight-chain carbon atoms. Owing to lack of suitable compounds, we have not been able to follow out this curve further; but it seems to indicate clearly that, between four and five carbon atoms, the orientation of the sorbed molecules changes from being pre-

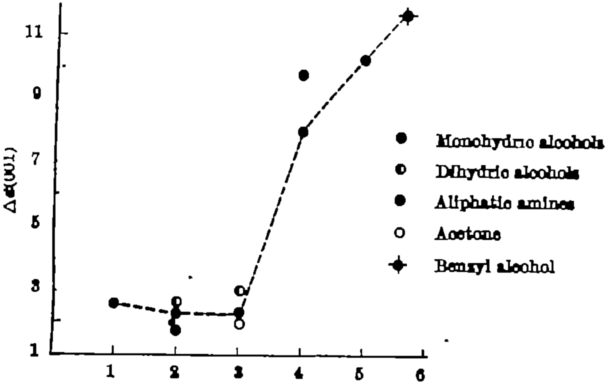

Fig. 1. Butanol and pentanol, in fact, give mixed spacings, only the larger one being plotted

dominantly 'lying down' to predominantly 'standing up'.

The alcohols may be supposed to react with the interlamellar acidic residues to give alkyl compounds: $C_4H_9OH + XOH \rightarrow C_4H_9OX + H_2O$. When the carbon chains are not too long, they can be accommodated in the parallel orientation; but when longer they have to seek another orientation. The observed Δ values for the longer chains correspond to straight-chain two-layer complexes of the type $C_4H_9.OXO.C_4H_9$. The existence of a mixture of spacings for butanol and pentanol may be due to the non-uniform nature of the substrate. It is noteworthy that benzyl alcohol (a much more bulky, though not much longer, molecule than pentanol) gives only the higher spacing.

The nature of the interlamellar acidic groups is not at present known with certainty, though further study of these complexes may throw light on it. According to R. Franklin[5], they would be complex anions of the form $(C_6H_y)_n$, but some acid groups such as $SO_4^{2-}$ are likely also to be present[3].

The amines probably form ionic, instead of homopolar, complexes: for example, ethylamine will give $C_2H_5NH_3^+.OX^-$. When upright, as apparently in the case of *iso*butylamine, they take up more space than the corresponding alcohols, as would be expected from the supposed difference in the nature of the bond. Aniline is an interesting case: it gives a spacing corresponding to an 'upright' orientation; but if sorbed from aqueous suspension it gives a still higher spacing, which appears to result from the introduction of two further layers of water molecules. Amines seem to be readily sorbed from aqueous solution, but not from benzene solution (in which they would not be ionized).

This work is supported by grants from the Consejo Superior de Investigaciones Científicas. A full account of it will appear in the *Anales de Física y Química*.

## Absorption Spectrum of Benzoquinone

The absorption spectrum of benzoquinone in the vapour state between 0° C. and 100° C. in cells 5–100 cm. long has been photographed with a three-prism Steinheil glass spectrograph and a Hilger *E* 492 quartz spectrograph. The molecule exhibits three systems of absorption—two in the ultra-violet and one in the visible region—as does the solution spectrum[1] of the substance.

That the bands in the ultra-violet form two distinct systems with two peaks of maximum intensity at about 2500 A. and 2800 A. is clear from the low-temperature spectrograms. At higher temperatures, however, the two systems overlap. The 2500 A. bands are very diffuse, broad and degraded on both sides, whereas the 2800 A. bands are less diffuse and are degraded to the red. About a hundred bands observed under different experimental conditions in this region were measured. The proposed analysis of the bands bears this out and shows that both systems are due to transitions allowed by symmetry. The 2800 A. band-system, however, has its zero band relatively less intense. Assuming $D_{2h}$ symmetry in the ground- and excited-states, the two systems appear to involve the transitions $B_{1u} \leftarrow A_{1g}$ (2500 A.) and $B_{3u} \leftarrow A_{1g}$ (2800 A.).

The visible bands lie in the region of 4100–5000 A. and consist of eight main groups developed at 100° C. in a 50-cm. cell. About 175 bands were measured in this region, including the twenty-eight bands reported previously[2]. These bands are very sharp, many of them having double and triple heads with separations of 7 cm.$^{-1}$ and 5 cm.$^{-1}$ between them. Some of the bands have a line-like appearance; but most of them are degraded towards the violet. One marked feature to be noticed is the appearance of the companion bands with separations of 36 cm.$^{-1}$ lying on the shorter wave-length side of the first band of each group. Companion bands also develop on the longer wave-length side of the main bands at a slightly higher temperature with frequency differences of 37 cm.$^{-1}$, 64 cm.$^{-1}$ and 92 cm.$^{-1}$. The accuracy is within 2 cm.$^{-1}$ for the sharp bands and 5 cm.$^{-1}$ for the broad bands in this region.

The analysis of this system offers several difficulties and interesting features. Treating the benzoquinone molecule as a *para* di-substituted benzene having $D_{2h}$ symmetry which is preserved on excitation, there is the possibility of the bands being due to a singlet-triplet transition[3] allowed by symmetry but forbidden by spin. The gross structure of the bands is, however, best understood when they are assigned to a symmetry-forbidden transition made possible by a non-totally symmetric vibration (for example, 538 cm.$^{-1}$ in the ground state and 520 cm.$^{-1}$ in the excited state). The forbidden transition appears to be ${}^1A_{1u} \leftarrow {}^1A_{1g}$ with the zero band at 21,512 cm.$^{-1}$.

McMurry[4] has suggested that the long-wave-length absorption in benzoquinone may be similar to the characteristic long-wave-length absorption of carbonyl compounds, which is due to a forbidden transition in which a loosely bound electron occupying a non-bonding orbital lying in the molecular plane and across the CO direction is excited to a higher molecular orbital with a node in the plane. The sharpness of the bands and the present analysis support this view. The analysis also shows that the forbidden character is due to symmetry rather than to spin. Further, if the analogy to the carbonyl compounds is true, it is clear that there is a shift from the aromatic character of the molecule as exhibited in the ultra-violet band systems to the aliphatic ketone character as exhibited in its visible system. There is evidence to show that this shift is gradual in the present case. The companion bands on the shorter wave-length side of the main bands appear to be due to $v,v$ transitions between vibrations of two different types in the two electronic states.

Details of this work will be published elsewhere.

## A Coal Seam as a Guide for Seismic Energy

A dispersive train of vibrations resembling an internal Love wave has been observed during seismic experiments in the Mangapehi State Coal Mine, New Zealand. The observation is of interest as suggesting that coal mines may offer peculiarly favourable conditions for the study of this type of wave, and also because guided waves may find useful applications in mining.

At Mangapehi a thick seam of sub-bituminous coal about 800 ft. deep is mined to a height of 9 ft. in the first working. The tests were carried out across a panel of solid coal, the shot-point being located in a mine sump. Fig. 1 shows the principal components of motion produced by a series of 2-oz. shots at a distance of 460 ft., as recorded by a portable seismic prospecting apparatus. The dispersive wave-train, which was the largest vibration recorded, appeared on the component parallel to the seam and normal to the direction of the shot-point (Fig. 1a).

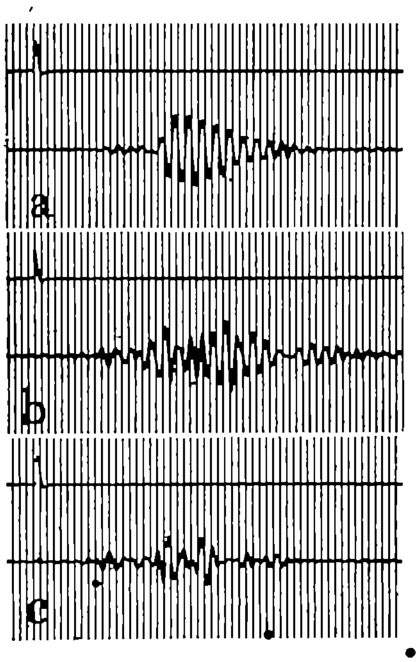

Fig. 1. Vibrations recorded at 460 ft. from source in Mangapehi coal mine. (a) Component parallel to seam and normal to direction of shot; (b) component parallel to seam and in line with direction of shot; (c) component normal to seam. The upper traces record the shot-instant, and timing-lines are at intervals of 10 m.sec. The sensitivity of the receiver for (b) and (c) was twice that for (a)

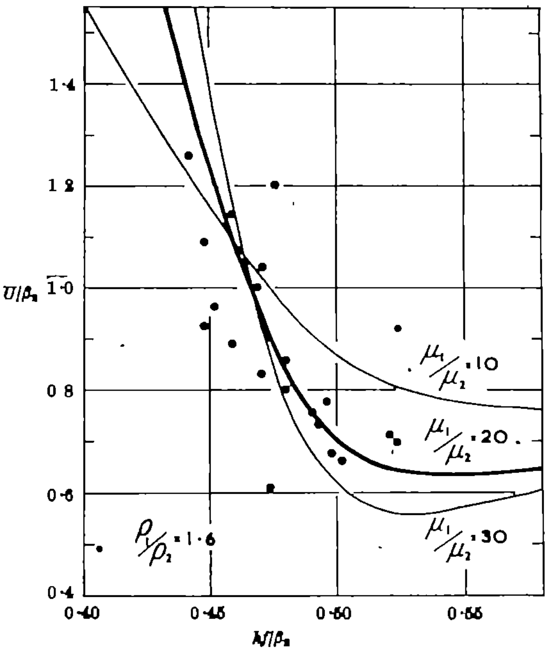

Fig. 2. Dispersion of wave-train in Fig. 1a plotted for comparison with that of theoretical Love waves. $U$ is group velocity and $f$ frequency. Subscripts 1 and 2 applied to the rigidity modulus $\mu$, density $\rho$, and shear velocity $\beta$, refer to the rock and the coal respectively. $h$ is thickness of the seam. Observations are plotted for $h$ = 17·6 ft., and $\beta_2$ = 1,900 ft./sec.

The dispersion of the wave is compared in Fig. 2 with the relevant portions of theoretical Love wave curves, which have been computed for a density ratio (rock/coal) of 1·6 and various rigidity ratios[1]. Apart from scatter (which may be attributed to other types of wave arriving at the same time), satisfactory agreement occurs for a rigidity ratio of 20 if the thickness of the coal is taken as 17·6 ft. and its shear velocity as 1,900 ft./sec. These values appear from other data to be approximately correct: the seam has been proved to be about 20½ ft. thick at a point some 650 ft. from the location of the tests; and in an opencast mine at Kimihia, where the coal is of similar rank, a compressional velocity of 3,000 ft./sec. in the coal has been measured, so that the shear velocity would not be very different from that indicated above. The large rigidity ratio is also corroborated in a general way from the time of travel of the first arrival (Fig. 1,b and c), which implies a compressional velocity of about 9,000 ft./sec. in the rock. A similar velocity was found in the measures under the coal at Kimihia.

Internal Love waves are propagated in a stratum of low shear velocity. Such strata are not uncommon in the Earth's crust, and numerous observations of guided waves have been reported[2]; but detailed studies would clearly be aided if observations could be made inside the guiding stratum. From published observations it seems probable that the shear velocity is commonly less in coal than in the coal-measure rocks[3]. The application of seismic pulse techniques to mining problems, such as that of locating faults, has been hindered by the high rate of attenuation in coal. With dispersive waves, however, times of travel may be determined from relatively low-frequency energy, which suffers less attenuation even apart from the guiding process. The records of Fig. 1 were obtained without electronic amplification.

## Electric Strength of Irradiated Polythene

The electric strength of irradiated polythene has been measured for material cross-linked by exposure to 4-MeV. electrons from a linear accelerator. Thin (1-mm.) moulded disks of material (average molecular weight, 17,000) recessed to a thickness of about 50 microns were irradiated *in vacuo* with doses of 150–300 Mrad , and the electric strength afterwards measured with direct voltage, using techniques described by Bird and Pelzer[1], and Ball[2]. Control results for normal material coincide with those of other investigations[1,3] to give curve *C* of Fig. 1; results for the irradiated material are shown by lines *A* and *B*. The changes in electric strength due to irradiation unexpectedly resemble those of Young's modulus for similar material measured by Charlesby and Hancock[4]. They are quite unlike those expected from the theory of intrinsic electric strength[5], which predicts for the cross-linked material a fall with temperature more marked than that of curve *C*, and beginning at a lower temperature.

One of us (C. G. G.) has shown that curve *C* above 60° C. and lines *A* and *B* above 80° C. correspond not to the intrinsic strength but to a previously unrecognized form of breakdown due to mechanical deformation. This produces a marked difference in the curves for normal and irradiated polythene because the modulus of elasticity for the former falls to zero at the melting point, whereas the irradiated material has a region of entropy-elasticity covering at least 100 deg.°C. above the normal melting point, in which the modulus rises slightly with temperature.

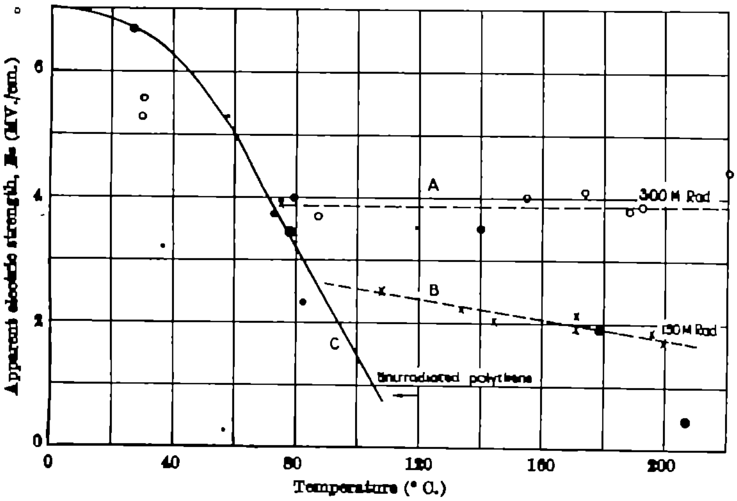

Fig. 1. Electric strength of polythene irradiated with 4-MeV. electrons; values calculated from the initial sample thickness

The mechanical pressure due to the electric breakdown stress is large, of the order of $E^2$ atmospheres ($E$ in MV./cm.). The thickness of the specimen, initially $t_0$, therefore decreases as the voltage ($V$) is raised, until either the intrinsic stress ($E_i$) is reached at a reduced thickness $t$, or until (as shown later) no stable thickness exists. Exact analysis for recessed specimens is impracticable; but the breakdown channel is so much smaller than the thin part of the recess that the case of a plane slab, laterally unconstrained, with electrodes free to follow the material, must be a rough approximation. The equilibrium thickness of the slab is given by:

$$\frac{\epsilon}{8\pi}\left(\frac{V}{t}\right)^2 = Y \log \frac{t_0}{t} \qquad (1)$$

where $Y$ is Young's modulus and $\epsilon$ is dielectric constant; units are C.G.S. and electrostatic. (The logarithmic form of the stress–strain relation is used because the strains are large.) Since $t^2 \log (t_0/t)$ has a maximum value when $t/t_0 = \exp -\frac{1}{2} \approx 0{\cdot}6$, no real value of $V$ can produce a stable value of $t/t_0$ less than 0·6. If the intrinsic strength has not been reached at this value, further increase of $V$ makes the thickness unstable, and it collapses, at a critical electric stress;

$$E_y = (4\pi Y/\epsilon)^{1/2} \text{ E.S.U.} \qquad (2)$$

The highest apparent electric strength which can be observed is therefore:

$$E_a = V/t_0 = (\exp -(\tfrac{1}{2})E_y) \qquad (3)$$

If $E_i$ is greater than $E_y$, the former is unobservable by the present technique; if $E_i$ is less than $E_y$, intrinsic breakdown occurs. $E_i$ can then be deduced from $E_a$ by means of equation (1) and lies in the range $E_a < E_i < (\exp \tfrac{1}{2})E_a$.

This analysis ignores several factors, such as possible earlier instability at microscopic areas of stress concentration, the dependence of $Y$ on time and stress, and plastic flow. These are difficult to calculate; but all tend to a lower value of $Y$. The analysis also applies only to materials sufficiently rubber-like to withstand severe distortion without fracture.

Since the compression involved is only 20 microns, in an object at high temperature and high potential, we have not yet attempted to observe it directly.

Values of $Y$ for irradiated polythene are given in Fig. 4 of ref. 4, one dose unit of this figure corresponding roughly with 100 Mrad. The values are only roughly correct for our specimens, since none of the experimental factors is exactly similar. For normal material, the values of ref. 4 and those of the makers differ by a factor of 4; we have taken the smaller (the makers') as nearer to our conditions of large strain. Breakdown values calculated from these data, using equation (3), are compared with observed values in Table 1, with as good agreement as could be expected from the data. The minimum calculated intrinsic strength for the 300 Mrad. material is 6·3 MV./cm. up to 220° C., and shows no evidence of fall with temperature.

Table 1

| Dose (Mrad.) | Temp. (° C.) | $Y \times 10^{-7}$ (dynes/cm.²) | $E_c$ (MV./cm.) | | $E_i$ (MV./cm.) Calc. from $E_c$ (obs.) |
|---|---|---|---|---|---|
| | | | Calc. | Obs. | |
| 150 | 150 | 2·5 | 2·2 | 2·1 | 3·5 |
| 300 | 150 | 5 | 3·1 | 3·8 | 6·8 |
| Nil | 60 | 18 | 5·8 | 5·0 | 5·9† |
| Nil | 80 | 9 | 4·1 | 3·2 | 5·3 |
| Nil | 100 | 5* | 3·1 | 1·5 | 2·5 |

* Uncertain due to plastic flow

† Value calculated from equat (1), intrinsic breakdown being reached before the critical stress of equat (2).

It may be remarked that tests with fixed electrodes would not eliminate the mechanical pressure, since at these high electric stresses field-emission readily occurs, and the charges which are subject to the electrostatic force are on the surfaces of the dielectric.

Further confirmation of the new mechanism has been obtained from existing data on poly*iso*butylene. The rapid change in electric strength[3] near − 40° C. is accurately predictable from the corresponding change in the modulus of elasticity[4].

For several other thermoplastics previously measured, $E_c$ (from equation (3)) should lie, for room temperatures, between 10 and 100 MV./cm., so that observed values of intrinsic strength between 5 and 10 MV./cm. are presumably genuine, but with no large margin between $E_i$ and $E_c$. It is possible that a material of high dielectric constant, and therefore subject to exceptionally high compressive stress, may fail by fracture even at low temperatures. All existing data on thermoplastics above room temperature must certainly be suspect.

We are indebted to the Metropolitan-Vickers Electrical Co., Ltd. (Radiation Laboratory), for irradiation of specimens, and to the Director of the Electrical Research Association for permission to publish the results.

## An Electronic Computer for the Evaluation of Results of Filter-Paper Electrophoresis

WE have described previously[1] an electronic apparatus for scanning filter-paper electropherograms, whereby curves showing the distribution of separated components are caused to appear on the cathode-ray tube of an oscilloscope. It has been used so far mainly for the analysis of mixtures of proteins.

The purpose of the present communication is to report upon the further development of the apparatus by the incorporation of an electronic integrator, which permits the rapid and accurate evaluation of the area enclosed under the whole or any selected part of such a distribution curve. By this means the quantity of each of the components corresponding to the separate peaks on an electropherogram, expressed as a percentage of the total material, can be read directly from a meter.

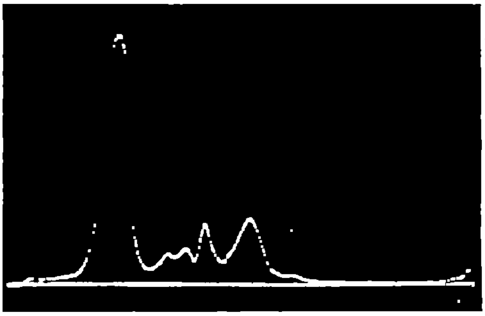

Fig. 1

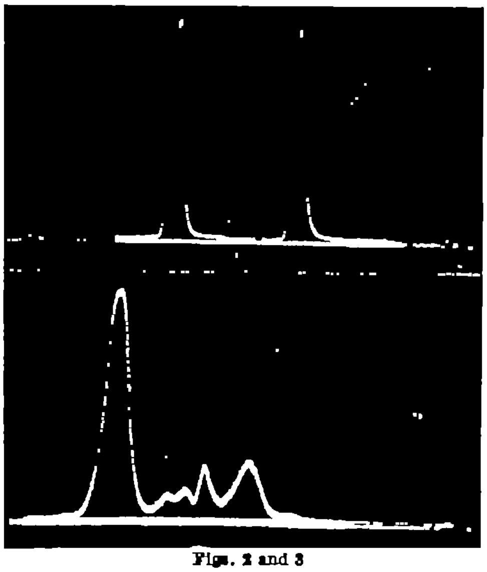
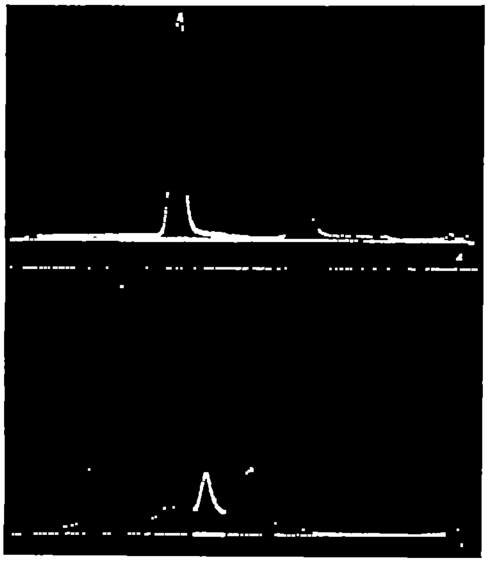
The basic system includes a well-stabilized power supply, an optical system and a metal drum on which is fastened the filter paper (30 cm. × 4 cm.) with the stained serum proteins. The drum is rotated and the paper illuminated with a narrow beam of light (0·5 mm. × 38 mm.). The reflected light from the filter paper is collimated on to a photomultiplier (*RCA*-931*A*). The current generated by the photomultiplier is passed into a special synchronizing circuit in order to obtain a steady picture of the distribution curve on a cathode-ray tube. The latter is used only as a visual indicator during the operations involved in actual evaluation.

To this basic system has been added a correcting exponential amplifier (cf. Beer–Lambert law), the output of which is fed into an electronic integrator and also into the cathode-ray tube in order to produce the ordinate. Since the Beer–Lambert law has been found to apply, the height of the curve represents directly the dye concentration at any given point along the filter paper without any further corrections. A typical distribution curve (or ordinate) for a normal rabbit serum is represented in Fig. 1. The accompanying photographs illustrate briefly the principles of the computation.



Figs. 2 and 3



Figs. 4 and 5

On a filter-paper strip there were applied two bands each with 0·01 ml. of a 6·5 per cent solution of purified human albumin. The strip was then subjected to electrophoresis for a short time, and the protein was stained with amido-black 10*B*. The curve shown in Fig. 2 is the result of the scanning of this strip by the instrument. The straight base-line under the distribution curve is produced electronically. The level of this line corresponds to the lowest portions of the distribution curves, that is, to those regions of the filter-paper strip where no protein is present. With the aid of a controlling potentiometer, the lowest point of any curve produced can be adjusted to the base-line level. By means of a sensitivity adjustment, the area between the distribution curve and this base line, which in Figs. 2 and 3 is shown by thicker lines, is adjusted to a reading of 100 on the meter. The setting of the sensitivity control necessary to make this adjustment can, by suitable calibration, provide a measure of the total amount of dye bound to the protein, provided that a standard method of staining and decolorization is used.

Two phantastrons enable any portion of the curve to be selected for electronic integration. The reading on the linear scale of the meter then gives directly the percentage of the total stained material represented by this section of the curve. Fig. 4 demonstrates this procedure applied to the results shown in Fig. 2. The part of the curve selected appears as a thicker line. The reading of the meter will then give the percentage of the whole area which is under this part of the curve.

Fig. 5 similarly illustrates the evaluation of the beta globulin of the serum pattern shown in Figs. 1 and 3. These examples demonstrate that, with the aid of the instrument, the separated proteins on the filter-paper strip can be evaluated directly in percentages of the total protein without further treatment of the paper or mathematical operations on the data. About two minutes are necessary to perform a complete evaluation of one strip.

This project was supported by grants awarded by the Department of National Health and Welfare and the National Research Council. We thank the late Dr. D. T. Fraser, Dr. Frieda Fraser and Dr. M. H. Brown for their help and encouragement, and Dr. O. Smithies and Dr. C. S. Hanes for help in the preparation of this communication.

## Detection of Labile Photochemical Free Radicals by Paramagnetic Resonance

PREVIOUS applications of the method of paramagnetic resonance to the detection of labile free radicals have been restricted to those stabilized by permanent trapping in polymers[1] or plastic films[2] at room temperature or those produced by γ-irradiation[3]. Measurements have now been made on radicals formed photochemically by ultra-violet irradiation of solutions frozen at liquid-oxygen or nitrogen temperatures. The radicals can be preserved for some hours at the low temperature, but their high reactivity is demonstrated by the rapid disappearance of the paramagnetic resonance signal on warming. The method of trapping free radicals by photolysis in rigid glasses at liquid-nitrogen temperature has been described by Norman and Porter[4], who used ultraviolet absorption spectroscopy to detect and identify the photochemical products. We have investigated several of the compounds used by Norman and Porter, and in addition we have demonstrated the production of free radicals in systems where they have not been previously observed.

The paramagnetic resonance apparatus was of standard crystal-video detection type operating at 3·2 cm. wave-length. The resonator, working in the $H_{011}$ mode, was specially designed so that the samples could be inserted along the central axis while still cooled to liquid-nitrogen temperature. The signals obtained were displayed on the screen of an oscilloscope. The solutions were frozen in small thin-walled silica tubes and irradiated at the temperature of liquid oxygen or nitrogen with light of wave-length 254 or 366 mμ. All solvents were spectroscopically pure and when irradiated under identical conditions produced no detectable paramagnetic resonance absorption. Using radiation of wave-length 254 mμ and liquid nitrogen, paramagnetic resonance absorption corresponding to free radicals was detected in the following substances: ethyl iodide, toluene, benzylamine, benzyl chloride and benzene in solution in P.HeH[4]; toluene in solution in E.P.A.[4]; hydrogen peroxide in water; oxalato complexes of the ferric, cobaltic and uranyl ions in ether–alcohol–water mixtures. Free radicals were also produced from the oxalato–ferric solutions at both liquid-oxygen and liquid-nitrogen temperature by irradiation with light of wave-length 366 mμ. The presence of air did not appear to affect the formation of free radicals.

Fig. 1*a* shows the absorption line obtained from a mixture of hydrogen peroxide and water. This had a *g* value of 2·01 ± 0·01 with a width of 20 gauss and an intensity corresponding to approximately $10^{16}$ free radicals. Although the vapour-phase photodecomposition of hydrogen peroxide leads to the production of hydroxyl radicals, no direct observation of its trapped photolysis products has previously

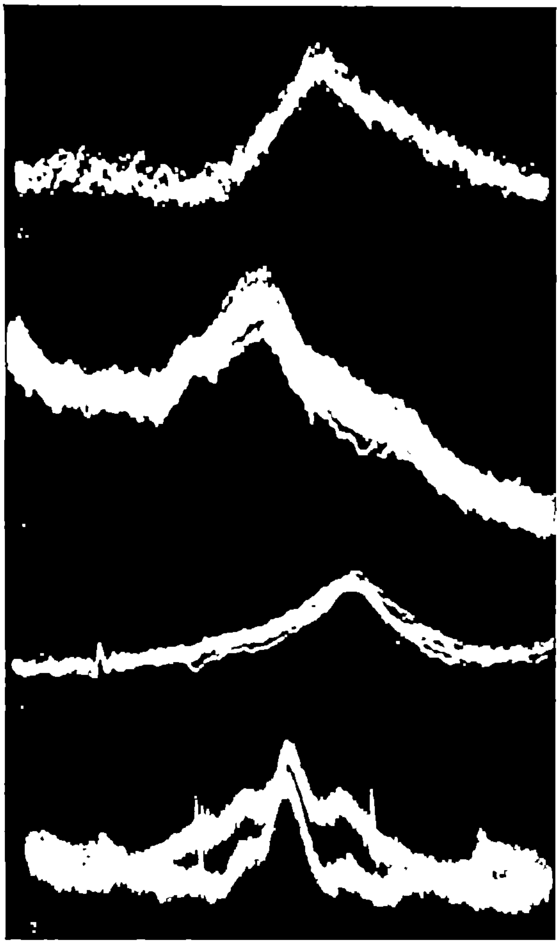

Fig. 1. Paramagnetic resonance absorption observed after ultra-violet irradiation at low temperature. (*a*) 40 per cent hydrogen peroxide in water. (*b*) Ethyl iodide in hydrocarbon mixture. (*c*) Oxalato-ferric chloride in ether-alcohol containing 8 per cent water (low homogeneity of field). (*d*) Oxalato-ferric chloride in ether-alcohol containing 10 per cent water (high homogeneity of field)

been made. The radicals were found to be quite stable at liquid-oxygen temperature but disappeared after storage for a few minutes at the temperature of solid carbon dioxide.

A typical signal obtained from irradiated ethyl iodide solution is shown in Fig. 1*b*. Neither iodine atoms nor ethyl radicals have previously been directly observed in this reaction, although the presence of iodine atoms has been inferred from the fact that the colour of the iodine molecule appears on warming irradiated glasses containing ethyl iodide[4]. The positive results obtained with toluene, benzylamine and benzyl chloride are also of particular interest in view of the spectroscopic evidence[4], which indicates that all three substances give rise to the same labile compound identified by Norman and Porter as the benzyl radical.

An oxalate radical has been postulated as the primary product in the photo-decomposition of ferric–oxalate solutions[5], and in view of the high and nearly constant quantum yield extending to 510 mμ[6], the possibility was investigated of producing and trapping the hypothetical radical by the use of comparatively low-energy radiation. Fig. 1*d* shows the signal obtained (with high homogeneity of field) from a solution of monoxalato-ferric chloride in ether-alcohol containing 10 per cent of water after irradiation in liquid oxygen with light of wave-length 366 mμ. A marked triplet structure is apparent which is attributed to proton interaction. On this basis the radical is tentatively identified as HCO$_2$ or HC$_2$O$_4$. Free-radical absorptions were observed in other oxalato-ferric solutions of varying composition, in all of which the monoxalato complex was the predominating species. Fig. 1*c* shows a typical absorption obtained with field homogeneity comparable with that used in the examination of the other compounds. A prominent feature of the irradiation of frozen ferric–oxalate solutions was the rapid formation of an orange-brown colour which disappeared on warming. The intensity of the colour was not directly related to the concentration of free radicals. It was produced in all the solvent mixtures investigated, including water only, and was particularly intense in solutions containing the trioxalato-ferric complex under conditions when no free radicals could be detected. The brown colour and its relation to the radical are the subject of a separate investigation.

Further work is planned using phase-sensitive detection and better field homogeneity, when the fine structure of the spectra should be more clearly resolved.

# Discrepancy between the Spectro-Isotopic and the Mass-Spectrometric Results for the Natural Abundance Ratio of the Lithium Isotopes

THE determination of the natural abundance ratio of the lithium isotopes lithium-6 and lithium-7 by spectroscopic measurement of the ratio of the line intensities of the isotopic components of the 6708 A. resonance line has given results not in agreement with the mass-spectrometric figure. A summary of the work in both fields up to 1951 has been given by Baldock and Patton[1]. In subsequent work on the spectro-isotopic assay, Stukenbroeker, Smith, Werner and McNally[2] calibrated the optical determination by samples analysed mass-spectrometrically and showed that the method could yield a $2\sigma$ precision of slightly more than 1 per cent using photographic recording.

A very thorough and careful investigation by Brody, Fred and Tomkins[3], in 1954, using both Fabry–Perot étalons and a 30-ft. Paschen–Runge spectrograph and employing direct recording, gave a result of 13·5 ± 0·2 for the natural abundance ratio. Full correction was for the first time made for self-absorption, but no mass-spectrometric results on the sample of lithium sulphate were quoted.

One of us (R. P. T.) has just completed a determination of the natural abundance ratio using Fabry–Perot étalons and photographic recording. The investigation differed only in detail from the American work of the previous year and yielded a similar result, namely, 13·5 ± 0·3. The lithium sulphate sample used had been examined by the mass spectrometer and a ratio of lithium-7 to lithium-6 of 12·2 ± 0·1 was found. No absolute calibration of the mass spectrometer has been yet carried out.

It was then realized that no correction had been made on the peak line intensities measured for the lines of the two isotopes.

According to White[4], the intensity at any point on the intensity frequency contour for the Doppler broadening of a spectral line is given by:

$$I(\nu) = \text{constant} \times \exp \frac{\mu}{2RT} \cdot \frac{c^2}{\nu_0^2} (\nu - \nu_0)^2$$

where $\mu$ is nuclear mass, $\nu_0$ is peak frequency, $c$ is velocity of light, $R$ is gas constant and $T$ is absolute temperature.

From this:

$$I(\nu) \text{ maximum} = \text{'constant'},$$

and the total integrated intensity:

$$\int I(\nu) d\nu = I(\nu) \text{ max. } \sqrt{\pi} \frac{\nu_0}{c} \sqrt{\frac{2RT}{\mu}}$$

$$= I(\nu) \text{ max. } 1 \cdot 772 \frac{\nu_0}{c} \sqrt{\frac{2RT}{\mu}}$$

For two isotopic lines, where the total emitted energy is equal and the two lines correspond to the same pair of initial and terminal term-levels, the values of $I_{\text{max}}$, that is, peak intensity, will be proportional to the square roots of the isotope masses; for example,

$$\frac{I_{\text{max}}\,{}^6\text{Li}}{I_{\text{max}}\,{}^7\text{Li}} = \sqrt{\frac{6}{7}}$$

The abundance ratio (${}^7$Li/${}^6$Li) based on the observed peak intensities of the isotope lines will therefore be $\sqrt{7}/\sqrt{6}$ of the true ratio, and a correction equal to the reciprocal of this, namely, $\sqrt{6}/\sqrt{7}$, should be applied to the observed abundance ratio.

When this correction was applied, the corrected natural abundance ratio was 12·5 ± 0·3, a result in very close agreement with the mass-spectrometric figure, and the mean of which lies within the range of 12·4–12·9 quoted by Cameron[5] for commercially prepared lithium salts.

It might now be said that the discrepancy between the spectroscopic and mass-spectroscopic determinations of the natural abundance ratio of the lithium isotopes has been reduced to the magnitude of the experimental errors of the two methods.

A search of the literature has shown that only in a very complete and precise investigation on boron by Mrozowski[6] has this Doppler correction been applied to the spectroscopic determination of natural abundance ratios.

Although a method has been worked out for the spectroscopic determination of the ratio of deuterium to hydrogen by Broida[7], conditions in the high-frequency discharge used are so complex that it is not possible to apply the large Doppler correction ($1/\sqrt{2}$); but it is of interest that the critical pressure at which the measured ratio equals the mass-spectrometric ratio varies as $\sqrt{D_2/H_2}$.

The isotope shift of the helium-3 and helium-4 isotopes has been measured by Fred *et al.*[8] but no line intensities are quoted.

This correction should apply significantly to the atomic line spectra of carbon ($\sqrt{12/13}$), oxygen ($\sqrt{8/9}$) and neon ($\sqrt{10/11}$), in addition to the elements quoted above.

## Radioactivity in Quartz Inclusions

THE method used by Ford and Ollier for recording the α-radioactivity of zircons[1] has served also to detect similar radioactivity in quartz inclusions.

The spherical cavities found in some specimens of quartz, of diameters ranging from 10 to 300 microns, are known to contain liquid and carbon dioxide gas[2]; but it is of interest to observe that some contain radioactive elements also.

A quartz microscope slide was covered with a film of Ilford *C2* photographic emulsion 50μ thick, and left for six months. After processing, certain cavities favourably placed with respect to the emulsion revealed tracks of α-particles. Into cavities in the surface, exposed during manufacture of the slide,

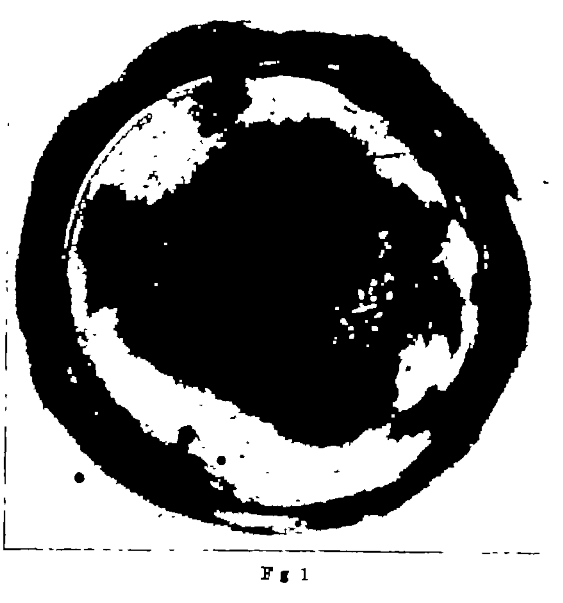

Fig. 1

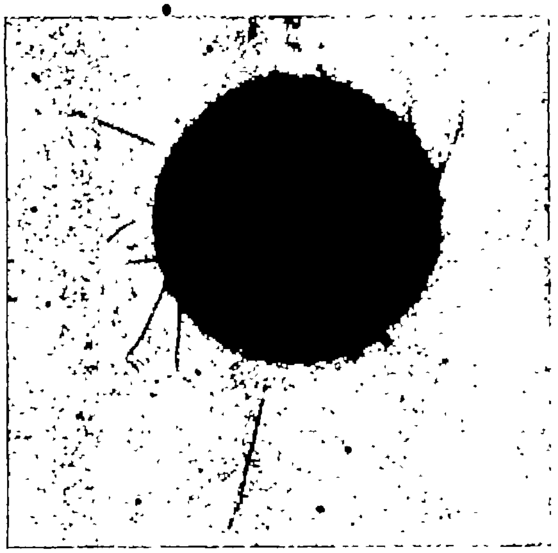

Fig. 2

emulsion had flowed (Fig. 1). Others, remaining intact just below the quartz surface, were near enough to the emulsion to send α-particles into it (Fig. 2). In one of the exposed cavities forty-two tracks of α-particles were counted. The longest, measuring more than 40μ, must have been emitted by a thorium C′ nucleus.

It is of interest to reflect that the interior of a quartz inclusion is apparently one of the rare places in the world where a whole radioactive series is in equilibrium.

## Definition of the Second of Time

SIR EDWARD BULLARD[1] solicits views on the desirability of abandoning the astronomical second for the most refined physical measurements, in view of the high precision[2] of atomic frequency standards. He suggests instead a 'physical second', to be defined in terms of the natural period of the cæsium atom, the advantage being that the physical second would be more immediately available than the astronomical second in cases where the highest precision is sought. The purpose of this communication is to direct attention to two consequences that should be well understood before the astronomical second is abandoned by physicists. I leave aside the question of desirability, on which views are certain to differ, because the change is desirable from some points of view and undesirable from others.

Many physicists have abandoned the metre as a standard of length and rely instead on the wavelength of a specified line of cadmium or mercury. For convenience, and in order to preserve the distinction between the two standards of length, it has been proposed (and for all I know may have been generally agreed) that the wave-length of the specified line stated in microns should be held fixed, the number of microns in a metre being subject to experimenta determination. To my mind, this convention is a admirable one.

In abandoning the astronomical second for th physical second, physicists would be proceeding in a entirely analogous way; and I think it would b advisable to abandon the word 'second', substitutin a new word that would stand for a unit of time havin an absolutely fixed relation to the natural frequenc of the cæsium atom, being very nearly a small aliquo part of a second, the exact relation being subjec to experimental determination.

The first of the consequences to which I wish t direct attention is that by using the atom at once a a standard of length and of frequency the units o length and of time lose their independence; wavelengths and frequencies have a fixed relation to each other, the product of the two being the velocity o light. Hence it is of the utmost importance that the new units should not be exclusively employed; atomic wave-lengths must be compared with the metre from time to time, and atomic frequencies must be compared with the astronomical second. To fail to do so would be unnecessarily to restrict the science of physics at its very foundations, by assuming what can only be verified by experiment. For this idea I am indebted to Prof. Jan Schilt, of Columbia University.

The second consequence arises from the fact that an atom, while it undoubtedly gives an excellent natural standard of frequency, is not a natural clock. It is probable that two cæsium standards built to the same specifications on opposite sides of the Atlantic would run at the same frequency; but if each were made to control the hands of a clock through a suitable mechanism, the two clocks would not indicate the same time (epoch). Even if they could be brought to the same time with enough precision to satisfy astronomers and geodesists —which is doubtful—if both should stop it would be impossible on starting them again to determine how much time had been lost. For actual timekeeping it will be necessary, as in the past, to rely on better mechanisms than man-made ones. The consequence, then, of adopting the new 'physical second' would be to use one second for measurements of frequency and another for actual timekeeping.

I remark, by the way, that Bullard is unnecessarily pessimistic about the reduction of the errors of astronomical observations by repetition; the systematic errors in star places and the differential refraction are not important limitations when periods of a year or more are considered. My own estimate is that with four dual-rate cameras observing the Moon, an accuracy of 1 in $10^9$ in time and frequency derived from astronomical observations can be attained in a year, and probably 1 in $10^{10}$ in five years. But Bullard's argument is not affected by these estimates.

It is to be hoped that before specifying the new unit of time, physicists will be willing to wait for the end of the International Geophysical Year, by which time a good number of observations of the Moon will have been made, and to compare atomic standards with astronomical ones assiduously in the meantime.

## FORTHCOMING EVENTS

### Wednesday, December 28—Saturday, December 31

Science Masters' Association (at the Royal College of Science, Imperial Institute Road, South Kensington, London, S.W.7)—Annual Meeting.

### Wednesday, December 28

At 8 p.m. (in the Courtauld Hall, Queen Elizabeth College, Campden Hill Road, Kensington, London, W.8)—Sir Edward Salisbury, F.R.S.: "Science and Education" (Presidential Address).

### Friday, December 30

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. A. W. Marshall: "How Clocks and Watches Work" (Juvenile Lecture).

## APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (with a good honours degree or Associateship of the Royal Institute of Chemistry, and with research and/or industrial experience) in Chemistry, at the Technical College of Monmouthshire, Crumlin—The Director of Education, County Hall, Newport, Mon. (December 30).

Assistant Lecturer (male, single, with a university degree or diploma in horticulture and a sound knowledge of practical horticulture) in Horticulture—The Principal Agricultural Officer, Lancashire County Institute of Agriculture, Hutton, near Preston (December 31).

Scientific Officer (honours graduate, with qualifications and research training or experience in microbiology or biochemistry or both) for work on the nutrition of marine micro-organisms and plankton, with particular reference to the role of vitamin $B_{12}$—The Secretary, National Institute for Research in Dairying, Shinfield, Reading (December 31).

Assistant Experimental Officer (with G.C.E. (advanced) or pass degree, or equivalent qualification) for laboratory and field work in plant pathological research on potato diseases—Officer in Charge, Agricultural Research Council, Potato Storage Investigation, c/o School of Agriculture, Sutton Bonington, Loughborough (January 1).

Electronics Technician (with experience in pulse techniques and in design, construction and general maintenance of equipment used in nuclear research) to take charge of the electronics laboratory, workshop and stores in the Research School of Physical Sciences, Australian National University, Canberra, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (January 6).

Assistant (with a degree in electrical engineering, and preferably with some research or industrial experience) in the Department of Engineering—The Secretary, The University, Edinburgh (January 15).

Chemists or Chemical Engineers (with a good honours degree in chemistry or chemical engineering) for research on the processing of liquid and gaseous by-products obtained during novel methods of coal carbonization—The National Coal Board, Coal Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting Ref. No. 83/138 (January 17).

Assistant Lecturer (graduate in physics, chemistry, metallurgy, biology or engineering) in Dental Materials—The Registrar, The University, Manchester 13 (January 18).

Lecturer or Senior Lecturer in the Department of Electronic Engineering, and a Lecturer in the Department of Electric Power Engineering—The Registrar, The University, Liverpool (January 21).

Scholar (with a good honours degree in physics) in the Geophysical and Meteorological Section of the School of Cosmic Physics—The Senior Clerk, Dublin Institute for Advanced Studies, 64 Merrion Square, Dublin (January 21)

Lecturer (with a first-class honours degree in mathematics, preferably with a special interest in some branch of applied mathematics or statistics) in Mathematics—The Registrar, College of Technology, Manchester 1 (January 23).

Coal Survey Officer, Principal Technical Officer or Senior Technical Officer grade (with a university degree in science, applied science or fuel technology, or equivalent qualifications, with experience in collection of samples and the complete analysis of coal), in the Coal Research Section, Commonwealth Scientific and Industrial Research Organization, Delhi Road, North Ryde, New South Wales, Australia, to organize and supervise the collection, preparation, testing and chemical analyses of coal samples—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 480/152 (January 28).

Chair of Pathology—The Registrar, The University, Leeds 2 (January 31).

Lecturer (with an honours degree in engineering) in Mechanical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (January 31).

Lecturer (with qualifications in theoretical physics) in Physics—The Secretary, Queen's University, Belfast (January 31).

Physicists (2) (with at least a second-class honours degree in physics and preferably with some research experience) for work on the electrical and optical properties of non-metals—The Professor of Physics, The University, Reading (January 31).

Research Assistant (with a university degree in an engineering or physical science) in Chemical Engineering, and a Lecturer (preferably with a university degree in engineering or in a physical science) in Chemical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (January 31).

Reader in Experimental Physics at Royal Holloway College, Englefield Green, Surrey—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 7).

Lecturer or Assistant Lecturer (with special interests in physico-organic chemistry) in Chemistry—The Secretary, The University, Exeter (February 11).

Chair of Applied Physical Chemistry—The Faculty of Engineering, The University, Alexandria, Egypt (February 15).

Lecturer (with experience in the field of electronics or radio communications) in Electrical Engineering at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, February 28).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics, and subjects allied to chemistry and physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Assistant, Grade A (with B.Sc. or A.R.I.C.), at Coventry Technical College, to teach chemistry mainly for O.N.C. and Inter. B.Sc. courses—The Director of Education, New Council Offices, Coventry.

Assistant Experimental Officers (at least 20 years of age, and with H.S.C. in science subjects, or equivalent qualifications) in the Health Physics Division, to assist in the control of radiation hazards in a variety of laboratories and engineering operations involving a very wide range of radioactive materials—The Establishment Officer, U.K. Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 459.

Assistant Experimental Officers (with at least H.S.C. in science subjects or equivalent qualifications, and preferably with experience of industrial water treatment techniques) in the Engineering Services Division, to carry out the more precise analytical work needed for the chemical service to new water moderated reactors, and to supervise less qualified staff; and (*b*) to operate a chemical service for novel experiments connected with the development of new reactors—The Establishment Officer, United Kingdom Atomic Energy Authority, A.E.R.E., Harwell, Didcot, Berks, quoting Ref. No. 462.

Assistant Trials Officer (with a degree in botany or agriculture or equivalent qualification, with practical experience in crop production) to work at Seale-Hayne Agricultural College, Newton Abbot, Devon, and Leeds University Farm, Headley Hall, Yorks—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Mathematicians (2) (with an honours degree) for research concerned with practical numerical problems capable of solution on computers, and involving work on such problems on machines available to the Corporation—The Secretary, National Research Development Corporation, 1 Tilney Street, London, W.1.

Physicists and Electrical Engineers, Scientific Officer or Experimental Officer grade, at a Ministry of Supply Armament Research and Development Establishment, near Sevenoaks, Kent, for (*a*) experimental design, development and operation of physical measuring apparatus, and (*b*) research and development work on weapon systems, in particular fuse techniques—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.452/5A/MF.

Research Assistant (with a B.Sc. degree, preferably with honours in chemistry) to assist with a research project of an organic/biochemical nature—The Secretary, Biochemistry and Chemistry Department, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Research Officer (with a university degree in forestry, or a university degree in botany and a diploma in forestry) in the Department of Forest Research, Federation of Nigeria, to carry out sylvicultural investigation, chiefly in the highest forest regions of the Federation, but with a possibility of work in the savannah regions also—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.61/14/06.

Technical Librarian (female, with previous experience in technical library work, a science degree or recognized qualification in librarianship, or both) for the Director of Research, 55 Broadway—The Recruitment and Training Officer (F/EV 557), London Transport Executive, 55 Broadway, London, S.W.1.

# SECURITY REGULATIONS AND THE CIVIL SERVICE

AN outstanding feature of the Geneva Conference last August on the peaceful uses of nuclear energy was the extent to which it restored the old spirit of scientific co-operation. Dr. A. H. Snell, director of the Physics Division of the Oak Ridge National Laboratory, for example, in his "Geneva Diary" in the *American Scientist*, recorded the opinion that the inhibitions of secrecy are no longer a controlling factor but are vestigial, and have been replaced by mutual scientific respect and by a sense that everybody is working on the same big job. Prof. I. I. Rabi, in expressing his own satisfaction with the results of the Conference in re-establishing the world-wide community of scientists, quoted a speech made to Hungary over the Moscow radio by Prof. V. Veksler to much the same effect, and noting the incentive for the mutual exchange of views that the Conference has given.

The significance of this Conference in re-establishing the contact between scientists and the conditions for the exchange of ideas upon which scientific advance depends is thus widely appreciated by scientists in all countries. It would appear, however, from the Prime Minister's very cold and reserved statement in the House of Commons on November 22, that political circles have yet to appreciate the importance of such freer interchange of views and of knowledge, not only from the point of view of scientific and technical advance, but equally from the point of view of preventing waste and duplication of effort. There is, it is true, still much to be done in this respect, and scientists generally could use the success of the Conference to illustrate the importance of freedom of discussion and of exchange of information as providing an essential condition for unimpeded scientific advance and for the most effective use of man-power and materials.

That aspect has been kept well to the fore in much that has been written on the security issue in the past ten years. It is well put, for example, in a symposium of papers on "Internal Security and Civil Rights" published in the *Annals of the American Academy of Political and Social Science* last July, particularly in those of Dr. R. M. Hutchins on the meaning and significance of academic freedom and of Prof. M. S. Livingston on science and security. With Dr. H. Tayler's account of the dismissal of professors who, invoking the Fifth Amendment, refuse to answer political inquiries in public, they help British readers to a clearer understanding of some puzzling incidents in the United States, as well as setting the whole question of science and academic freedom and security in its proper perspective.

This symposium is particularly welcome at a moment when the debates in Parliament on the disappearance of the former Foreign Office officials, Burgess and Maclean, and the subsequent appointment, announced by the Prime Minister on November 23, of a Conference of Privy Councillors to consider security precautions, brought security measures and secrecy again to the front in Great Britain. If, for example, there is to be any relaxation of secrecy in the field of nuclear energy, there must not only be public understanding of the value and importance of such relaxation, but equally public confidence that the precautions against disregard of what secrecy or security measures are retained are adequate and effective. The Conference, which includes the Lord President of the Council and six other members, is to examine the security procedures now applied in the public services of Britain and to consider whether any further precautions are called for and should be taken.

Much of the investigation of this Conference must obviously remain secret, though the Prime Minister said that any recommendations involving changes in the law would be referred to the House of Commons. It was the more unfortunate, accordingly, that neither in the debate in the House of Commons on November 7, nor in that in the House of Lords on November 22, were the wider issues really discussed. While the debates did something to remove public misgivings about the British security system, they were over-occupied with personal and transient aspects of the unhappy episode. The Foreign Secretary, Mr. Harold Macmillan, indeed stated that a regular system of positive vetting has been introduced in all Government departments having access to classified material involving the security of the State, and that in the Foreign Office the practice goes far beyond the recommendation of the committee appointed by the Foreign Secretary, immediately after the disappearance of Maclean and Burgess, to look into all aspects of the security arrangements in the Foreign Office. Not only all members of the senior branches and the senior grades of the junior branches of the Foreign Service are covered, but also many more junior grades who are inevitably employed on highly classified work. The committee, moreover, considered that character as well as political reliability should be assessed, and fresh instructions to that effect had been issued by the Permanent Under-Secretary of the Foreign Office to heads of missions and other senior officials before the committee reported.

Mr. Macmillan was emphatic that there could be no doubt of the skill, perseverance and loyalty of the Security Service, and that we had been able to recruit men of remarkably high character and attainments. He doubted whether any substantial further improvements in our security arrangements could be made within our existing system of law; but recognized that this and other incidents in the world of science have had a serious effect upon our reputation abroad. He said it is of the greatest importance that confidence should be felt that successive Governments have taken all steps within their power to stop any loopholes and to strengthen any legitimate methods of defending the vital secrets of the country.

Mr. Macmillan, in concluding, pointed out the real difficulty in this new situation that confronts us, of reconciling security with the maintenance of a free society in the face of enemies who recognize no restraints. In the effort to preserve tolerance in the face of intolerance, it is all too easy to destroy freedom. As the Prime Minister said, it is probably true that if the Security Service had the powers which are possessed by such services in other countries, Burgess and Maclean would not be where they are to-day. Sir Anthony Eden added that he is not prepared to be Prime Minister of a Government which would ask for such powers of the House. Mr. Alfred Robens, who had reminded the House specifically that the attitude of our allies, and particularly of the United States, to the exchange of atomic secrets is conditioned by the degree of their confidence in our security arrangements and our ability to ensure that secrets entrusted to us will not pass to a foreign Power because of the laxity or inefficiency of our Security Services, agreed that we want security without McCarthyism. None the less, neither the Prime Minister nor the Foreign Secretary really faced the issue over passports, and any legal uncertainty should have made action easier rather than otherwise.

It is on this point that doubts have arisen as to the vigilance of the Foreign Office, on which some rather extreme and ill-judged criticism has been founded. It has been argued that issue of a passport is a privilege, not a right, and that a privilege can be withdrawn at the discretion of the Government. In particular, it has been suggested that those occupying posts involving access to highly secret information should be required to surrender their passports, which would only be available to them on notification of their intention to proceed overseas. During wartime, some procedure of this kind could well be formulated which would not restrict freedom of movement but merely ensure that those engaged in certain categories of work gave prior notification to a responsible officer of their intention to go abroad; but clear thinking on this matter is essential. The general issue is well put by J. A. Fanelli in an article, "Passport—Right or Privilege", contributed to the symposium already mentioned. Mr. Fanelli would make passports a right for every citizen—not sought by legal process; but while he condemns the present practice in the United States, which has been the subject of weighty protests so far as scientists are concerned, he would not object presumably to such a process as that just suggested. Incidentally, in Great Britain, as was pointed out by the Minister of State for Foreign Affairs on November 1, in theory, the Foreign Secretary has the power to withhold or withdraw a passport at his discretion.

The issue is one on which scientists themselves should be thinking constructively. Stray references in the debate in Parliament showed that members were thinking of scientists in relation to security, and that it was recognized as important to take the same care in vetting for employment in secret research work in industry as for employment in the Government service. Such requirements have to be reconciled, moreover, with the maintenance of the conditions under which a scientist, and especially the research worker, can give of his best, and secure stimulating contact with other minds. What matters above all at the moment in regard to this issue of security and secrecy in relation to science is that the right questions should be asked—the questions which scientific advance no less than the national security suggest.

Those questions are well indicated both by Dr. Hutchins and by Prof. Livingston, and their papers are not the less relevant in the discussion of British security measures in that those measures have avoided the grosser errors of which they, and other contributors to the symposium, complain. It is difficult for the non-scientist to keep clearly in mind in this context the way in which progress and leadership in science and national security alike depend on the number and quality of trained minds we can command, or to appreciate that because our intellectual potential provides the greatest security as well as our major resource, to secure the conditions which foster imaginative thinking is as important an element in defence policy as in research policy. Further, to carry restrictive conditions to a point beyond the indispensable minimum not merely hinders such thinking but may also endanger security by discouraging the recruitment of the very type of mind most required.

That we need reliable people in positions of responsibility and especially in secret investigations is obvious; but much keener thinking about the purposes of a security system and the way it functions is desirable than was manifest in either debate in Parliament. Moreover, the references to recruitment never touched on the real issue—the effect of security procedures on the recruitment of men and women of the character and ability most desirable in the service of the State. If we fail to put the proper emphasis on competence, and if independent thought and criticism are at a discount, we may get government servants who are loyal, but we may not get with that loyalty either the enterprise or the competence and vision that to-day are supremely important for the maintenance of national security.

Nor does the report of the Royal Commission on the Civil Service* really discuss this factor. The Commission was, indeed, limited by its terms of reference to the consideration of the principles which should govern pay, but including such matters as hours of work, payment for extra duty, annual leave, etc. It recognizes clearly that these conditions did not permit it to explore or comment upon ways in which recruitment might be improved and the Service made more attractive to possible recruits. None the less, the Commission points out that career prospects bear closely on the recruitment of suitable staff, and it is remarked that a review of recruitment procedures might indicate possibilities of improving the present situation. In the face of the competition, on which some comment was made in evidence to the Commission, it is obvious that the time a candidate sometimes has to wait before he is offered a post loses the Service many desirable candidates, and it may well be that this is one factor contributing to the acute recruitment difficulty of which the Atomic Energy Authority also complained in its first annual report.

---

* Report of the Royal Commission on the Civil Service, 1953–55. Pp. viii+238 (Cmd. 9613.) (London: H.M. Stationery Office, 1955.) 6s. 6d. net.

Apart from its bearing on this question of recruitment generally and the effect on the quality of the candidates who present themselves, the report of the Royal Commission on the Civil Service makes little direct contribution to this security issue. The primary principle laid down by the Commission, that Civil Service pay should be based on a "fair comparison with the current remuneration of outside staffs employed on broadly similar work, taking account of differences in other conditions of service", is the only sensible principle. The public service, by its nature, cannot provide its own criteria of what is reasonable remuneration; and the standing advisory committee of distinguished men chosen to reflect a cross-section of informed opinion in the country, recommended by the Commission to advise the Government on the remuneration of the higher Civil Service, should help to avoid the danger of setting standards from within —a practice which the Commission rejects for the scientific class, in spite of the arguments of the Institution of Professional Civil Servants.

The evidence as to the effect of conditions in the Civil Service on recruitment is not altogether clear. The members concerned in the administrative class are too small to be assessed significantly in such a sample inquiry as that recently conducted by Political and Economic Planning, which suggested that the Civil Service is still obtaining, and holding, a reasonable proportion of university graduates, though possibly a lesser proportion of the first-class men than enter the Scientific Civil Service. The Civil Service Commissioners themselves, while considering that the quality of the successful candidates continues in general to be satisfactory, doubted whether the number of really outstanding candidates is quite sufficient for future needs, and would welcome another three or four such candidates a year. This view was generally endorsed by the departmental witnesses; and in the view of the Association of First Division Civil Servants, not enough of the ablest people from the universities are now entering the Service.

The opinion was expressed in evidence that the Civil Service does not require more than about twelve outstanding men a year. These should easily be obtained from the universities if reasonable conditions are offered; but it should also be remembered that, particularly as regards the scientific officer class, it is not in the country's interest that the Civil Service should attract more than a reasonable proportion of the scientific and technical talent of the nation. This was clearly recognized by the Commission, which stressed the importance of preserving as much flexibility as possible for complements in this field. Moreover, it emphasized the importance of adequate opportunities for such staff to transfer to administrative posts, both from the point of view of career, and as a means of ensuring that those responsible for policy are fully competent to appreciate the technical issues involved in its formulation.

That in itself has some bearing on the security issue, if secrecy procedures are to be formulated on a realistic basis, and will also be of increasing importance if the Civil Service is not to lag behind outside employment in the attractiveness of the scientific or professional career it can offer. It is also a prime safeguard in ensuring that there is a reasonable balance in the interchange between the Service and industry, over which the Ministry of Supply in particular is disturbed. Some such interchange is desirable, but the Ministry of Supply thought that superior financial inducements outside had led to excessive loss of senior men. The Commission was, however, strongly impressed by the view of the Barlow Committee that the best scientific men should have equal prospects of pay and promotion with the best men in the administrative class, at least up to the top of the principal grade. The chairman of the Interdepartmental Scientific Panel thought that the present position whereby the average man reached the grade of principal scientific officer by age thirty-six and the really first-class man at thirty to thirty-two was about right, but that the present proportion of posts above that grade was inadequate. He also suggested that while the special-merit promotion scheme was an outstanding success, and catered sufficiently for the exceptionally able research worker whose bent did not lie towards administration, more flexibility was desirable to enable the Service to retain people with administrative initiative and ability.

The Secretary of the Department of Scientific and Industrial Research also expressed the view that the disparity in career values between the administrative and scientific officer class should be reduced, and that some posts now in the deputy chief scientific officer grade would justify chief scientific officer grading. The Commission suggests alternative salaries rather than one figure for the chief scientific officer class, and sees no objection to increasing the number of posts in the scientific officer class with the same salary as the permanent secretary. It believes, however, that the position in the Service at the present time reflects that in outside employment generally, in that the comparatively small number of outstanding scientists are enabled to advance rapidly, while most men of average quality do not get much beyond a level of responsibility corresponding roughly to that of principal scientific officer.

This view finds some support in the recruitment position for, while the number of suitable candidates was below demand, the real vacancies were fewer in 1954 than in 1952 or 1953, varying according to subjects. There were more than sufficient applications from organic chemists and from biologists, but there was a nation-wide shortage of physicists and engineers. The Civil Service Commissioners believe that while the ablest scientists still make their career at the universities, of those just below the highest quality the Government recruits at least a fair share, that the standard of applicants is improving, and that in the next five years the Departments will obtain suitable men for a high proportion of their demands. Such recruitment difficulties as existed are ascribed to the national situation rather than to service conditions.

These views were generally endorsed by witnesses from the main departments employing scientific staff, and in this context the acute difficulty of which the Atomic Energy Authority complained in its first annual report may be a passing phase. The Authority, in fact, has rather more flexibility in regard to salaries than the Civil Service, and it is inconceivable that it is offering less attractive conditions in regard to equipment and the like than other Government establishments. These conditions, in fact, frequently give the Government service a considerable advantage with the research worker over other bodies or industrial firms, particularly if there is any substance in the view frequently expressed that an industrial career does not give the same prestige as an academic career with outstanding research work.

One possible explanation may be the severe screening to which many of the Atomic Energy Authority's staff are subjected. This inevitably reduces the number of eligible candidates, and apart from deterring some who would be eligible, the delay involved may lead to others taking employment elsewhere. The point is worth considering, for it is not only in work on nuclear energy that it is desirable to keep secrecy requirements and screening investigations to the indispensable minimum. The Conference of Privy Counsellors is charged with seeing that security measures in Britain are adequately conceived and effectively operated. It is no less important to see that they are wisely applied, and that they are not allowed to obstruct the nation's economy by being used where no real purpose is served. The restoration of confidence in the security measures operating in Great Britain and abroad is not simply a matter of seeing that they are adequate and are efficiently operated. It is no less a matter of seeing that they are limited to their proper field, and that the lines between military and non-military work on nuclear energy, for example, are drawn as clearly as possible. The philosophy which inspires the whole security system should be one which keeps secrecy in its proper place, and makes it the servant and not the master of policy, placing its reliance not on negatives but on the positive contributions which imaginative, alert and creative thinking make to our economy as well as to our system of defence. The remuneration offered in the Civil Service is still one factor which determines the power to attract recruits of the character as well as of the intellectual ability which that Service demands.

# THE PHILOSOPHY OF NATURAL PRODUCT CHEMISTRY

**The Structural Relations of Natural Products**

Being the First Weizmann Memorial Lectures, December, 1953. By Sir Robert Robinson. Pp. xii+150. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 25s. net.

THIS is a remarkable little book. Its distinction is twofold. First, it is, so far as I am aware, the first book that has been written by Sir Robert Robinson. Secondly, it represents the first series of Weizmann Memorial Lectures delivered at the Weizmann Institute, Rehovoth, in memory of Israel's late President.

Dr. Chaim Weizmann was widely respected for his scientific work, not only in Israel but also in all countries of the world where the science of organic chemistry is seriously pursued. An introduction to the volume under review by Dr. E. Katchalski, the present director of the Weizmann Institute, indicates something of the character of the man who is to be honoured in perpetuity and gives a glimpse of the respected place that science occupies in the new State of Israel. It need only be said that the first Weizmann Lectures are a worthy token of respect by one great man for another.

The main purpose of the book is to show how the constitutions of natural products can be broken down into smaller units. Once these smaller units have been recognized, they may be reassembled in different ways in order to provide structural formulæ which may, or may not, represent real natural products. The fundamental concept carries with it the implication that there is a relationship between the assembly of the hypothetical structural units and the real, but still largely unknown, processes of biosynthesis. It is somewhat paradoxical that the more complex the natural product the more easy it is, in general, to discern the structural units from which it is composed. It is largely for this reason that 'biogenetic concepts' have now become an important ancillary to more orthodox methods of elucidation of the constitutions of organic molecules.

The first lecture deals with the building up of fatty acids from $C_2$ residues, the modification of this scheme to include isoprene residues and the derived terpenoids and steroids, the development of carbohydrates and their congeners, the introduction of the $C_6$—$C_3$, the $C_6$—$C_3$—$C_6$ and the $C_6$—$C_3$—$C_3$—$C_6$ structural groups and some miscellaneous topics including mould products. The breadth of the field covered is such that no group of substances can be treated in any detail. Nevertheless, the integrating power of the method is so great, and Sir Robert's exposition so able, that the essential points are clearly presented. Any reader who is interested in, say, triterpenoid biogenesis will find the references that he needs to follow the full development of his speciality.

The application of 'biogenetic concepts' probably receives its finest expression in the field of alkaloid chemistry. It is in this branch of knowledge that Sir Robert's classical paper of 1917, describing the synthesis of tropinone, adumbrated clearly all subsequent developments. The second and third lectures present the various groups of alkaloids in order of increasing complexity. Again, it is the more complex compounds which tell us most about biogenetic pathways. For example, once the concept of the fission of the aromatic ring of 3 : 4-dihydroxyphenylalanine (or its equivalent) had been developed by Woodward to explain the biogenesis of strychnine, it was possible to correlate theoretically the strychnine and quinine groups of alkaloids. Furthermore, Sir Robert was even able to deduce the correct constitution for emetine. The achievements of the theory in alkaloid chemistry are indeed impressive.

The use of 'biogenesis' in the elucidation of the constitutions of organic molecules has had its critics, especially from the biological side. Nevertheless, it would seem philosophically improbable that such remarkable order as is presented in the book under review should not have a real basis in Nature. No one pretends that the units written down by the organic chemist, or even used by him in syntheses under 'physiological conditions', are really present in the plant. All that is claimed is that the *equivalents* of these units are available. We are just now beginning to see the fruits of tracer experiments, which should do much to place 'biogenetic concepts' on an even firmer theoretical basis. There is no clash here between the organic chemist and his more biologically minded colleagues. Provided that constitutional arguments by 'biogenesis' are used as a stimulus to critical experimental work—not as a substitute therefor—the method has much to commend it.

This book can be thoroughly recommended to all mature organic chemists and others interested in the subject. It is a little unfortunate that a work which deserves to be read so widely should be so comparatively expensive. D. H. R. BARTON

## CLASSICAL ELECTROMAGNETISM

### Electromagnetic Theory

By Prof. V. C. A. Ferraro. Pp. viii+555. (London: The Athlone Press (University of London), 1954. Distributed by Constable and Co., Ltd.) 42s. net.

PROF. V. C. A. FERRARO'S book "has been written to meet the requirements of students reading for an Honours degree course in Mathematics . . . it should also be of use to physicists and electrical engineers". Four-fifths of the book is devoted to the steady state (including steady currents and their magnetic fields); this part contains chapters devoted to special topics such as systems of conductors, images and inversion, steady-current networks and boundary-value problems in potential theory. After the introduction of electromagnetic induction and the development of Maxwell's equations comes a chapter on alternating-current theory and two chapters on electromagnetic waves. The book closes with a chapter on the motion of charged particles in steady electric and magnetic fields. There are an extensive collection of examples at the end of each chapter and a number of worked examples in the text.

The balance of emphasis between static and varying fields, and the necessarily brief account given of the applications of the theory, suggest that the book should be appraised primarily as an exposition of the fundamental principles of electromagnetic theory. For this exposition the author adopts the traditional method, proceeding from the electromagnetic field in free space to the properties of dielectrics considered as regions of distributed polarization, and then to the magnetic fields of permanent magnets and magnetic materials. The theory of the magnetic fields of steady currents is developed from the properties of the circulation integral, and the connexion between electromagnetic induction and the conservation of energy is explained.

This approach to electromagnetic theory undoubtedly has many advantages. It enables the student to obtain a firm grasp of the physical significance of the electric and magnetic field-strength and induction vectors by studying their simplest manifestations; and this familiarity with the basic concepts facilitates the understanding of their rather complicated interconnexions in Maxwell's equations. On the whole, the author has exploited well the advantages of his choice of method, and the result is a readable and lucid text-book of classical electromagnetic theory. The book is open to criticism, however, on important points of detail. For example: the introduction of the displacement current is based on an apparently arbitrary preference by Maxwell for closed currents; the treatment of the energy density of the magnetic field, on which the deduction of the law of electromagnetic induction depends, proceeds by unjustified generalization, from a formula developed for permanent magnets in free space, to systems containing permeable media and electric currents; the proof of an important formula for the energy of a distributed current system is based on the statement, which is several times repeated in other contexts, that the stream lines in a solenoidal field are closed curves; and even in a theoretical text-book one does not expect to find such statements as that "molecules become electric dipoles only through the action of the inducing electric field", and that in iron the intensity of magnetization is directly proportional to the magnetic field. E. WILD

## BRITISH MOSSES AND LIVERWORTS

### British Mosses and Liverworts

An Introductory Work, with Full Descriptions and Figures of over 200 Species, and Keys for the Identification of all except the Very Rare Species. Written and Illustrated by Dr. E. Vernon Watson. Pp. xvi+419+18 plates. (Cambridge: At the University Press, 1955.) 45s. net.

THE need for a simple flora dealing with the British bryophytes has been felt for a long time. It is true that the identification of the British species is well provided for by the handbooks of Dixon and MacVicar; but the comprehensive detailed treatment which makes these works so valuable is apt to be confusing and even somewhat forbidding to the beginner. Dr. E. Vernon Watson has now produced a clear and attractive introductory flora, which should be a great asset to anyone commencing the study of British mosses and liverworts. It has naturally not been possible to include all the British species in this shortened account; but, by omitting the rarities, identification of the commoner species has been greatly facilitated.

The principal morphological features of mosses and liverworts are simply and clearly described in the introduction and glossary, which should enable the book to be used successfully even by those with little previous knowledge of the bryophytes. Although full descriptions and drawings are given for only 154 species of mosses and 55 species of liverworts, the keys and notes provide in all for the identification of 310 mosses and 136 liverworts. Several practical trials have shown that the keys are easy to follow and are based on readily determined characters. A few numbers have evidently been omitted accidentally from the key on p. 59, but any such errors should give little difficulty and are not easy to avoid in the first edition of a book of this type. The detachable field-key is an innovation of doubtful value. Since only the commonest species are included, its use is sure to lead to disappointment on many occasions.

In a number of respects the book is an improvement on previous bryophyte floras. The drawings of the species selected for detailed treatment are particularly valuable; and include habit drawings as well as figures of details important for identification. The descriptions are straightforward but sufficiently full, and are accompanied by useful ecological notes. Habitat lists at the end of the book indicate the range of species most likely to be encountered in twenty-five different habitats, and should be of great value to those beginning field-studies of the bryophytes. Mention should also be made of the fine photographs, which illustrate the attractive appearance of some of the common mosses and liverworts.

It may be said in conclusion that Dr. Watson has succeeded admirably in his aim of providing a sound introductory flora of the British bryophytes. The British student is now well provided with floristic works; but there is still a great need for an introductory work dealing with the more general aspects of bryology. Anyone acquainted with the classical works of Hofmeister, Leitgeb, Goebel and others, and with the many recent contributions to the morphology, physiology, cytology, genetics and general biology of the bryophytes, will realize that taxonomic studies are only one approach to the many aspects of bryological science. A. Allsopp

## BLACK FLIES OF GUATEMALA

### The Black Flies (Diptera, Simuliidae) of Guatemala and their Role as Vectors of Onchocerciasis

By Herbert T. Dalmat. (Smithsonian Miscellaneous Collections, Vol. 125, No. 1, Pub. 4173.) Pp. 425 + 44 pl. (Washington, D.C.: Smithsonian Institution, 1955.)

In the New World onchocerciasis is endemic in certain areas in Guatemala, Mexico, elsewhere in Central America, and in Venezuela. In communities within these areas in Guatemala, the degree of infection may vary from 5 to 100 per cent, with an average of about 35 per cent. About half those infected suffer from ocular symptoms, and about 5 per cent suffer the most serious *sequela*, namely, blindness. It has been estimated that some thirty-five thousand persons in Mexico and some twenty-five thousand in Guatemala are infected. As in Africa, the infecting worms are transmitted from man to man by species of Simuliidae. Nuisance caused by the biting flies can also bring to a halt field-operations, particularly the harvesting of coffee, which is the most important crop in the endemic areas of Guatemala. Prior to 1934 only three species of Simuliidae were known from Guatemala; that year Bequaert[1] added three more. To anyone acquainted with the Simuliidae and able to read maps, this was obviously a quite unrealistic picture of the Simuliid fauna in a country like Guatemala. This book by H. T. Dalmat presents the results of nearly six years (1947–53) of intensive work on the Simuliidae in Guatemala, done with the support of various agencies and the Ministry of Health there. Forty-one species are dealt with and, of these, thirteen are ones that Dalmat has described as new in the course of his studies in Guatemala in earlier papers.

The various species are described in detail: both sexes, the pupa with its cocoon, and the mature larva when, as in most cases, diligent field-work or controlled rearing has provided them. No new species are described; but there are descriptions of sexes and stages not previously known. Keys for identification of the species in all stages are provided, and there are excellent series of figures of genitalia, etc., all drawn in the same style from uniformly prepared parts. Uniformity of style and preparation is important because parts such as the male claspers can give very different impressions of their characteristics if snipped off the abdomen at slightly different angles. The keys are restricted to the species known from Guatemala, and one therefore wonders if there is much real value in giving a key to the sub-genera of *Simulium*. All that this key does is to pick out three species which are the only representatives of their different sub-genera in Guatemala and then lead on to other keys to the remaining species of the other four sub-genera represented in the Guatemalan fauna. Only the more important and more recent references for each species are given, and the reader is referred to Vargas's[2] catalogue of "New World Simuliidae" for the complete literature up to the date of that catalogue (1945). The status of genera and sub-genera is not discussed.

Valuable and important as these systematic descriptions are, the parts of the book that will interest Old World readers most are probably those dealing with epidemiology (pp. 6–57) and ecology (pp. 313–372). Anyone proposing to carry out a survey of Simuliidae would do well to study Dalmat's approach and methods. The various tables, graphs, etc., obviously represent but a creaming of a vast amount of data collected.

In certain regions the rainy season is inimical to Simuliidae because the exceptional amounts of water scour large numbers of larvæ and pupæ from their substrates and wash them down-stream to conditions under which, even if they could gain a foothold, they would not survive. The coffee crop is usually concentrated in small patches cleared in the forest. At harvest large numbers of workers go to these coffee fields, and men especially will expose the upper parts of the body and roll up their trouser legs when picking the berries. Furthermore, while picking berries, the workers stand relatively still in one place and so present excellent targets for the flies. If the harvest coincides with a good emergence of adult Simuliidae, then conditions are ideal for spreading the infection of onchocerciasis, for the adult flies will travel considerable distances to obtain a blood-meal.

Only three species of *Simulium* appear to be of importance as vectors of onchocerciasis in Guatemala: *ochraceum* Walker, *metallicum* Bellardi and *callidum* Dyar and Shannon. These three are markedly anthropophilic in habit compared with the remaining species. Itinerant peddlers are a feature of Guatemalan village life, and they may possibly be a source of infection. The exact factors that control endemicity are not yet apparent: the principal vector seems to be *S. ochraceum* Walker; but the areas of endemicity do not extend to the margins of the distribution of this species.

The Smithsonian Institution is to be congratulated on the general format and production of this book, in which it has been assisted financially by the Pan-American Sanitary Bureau. John Smart

# COMBUSTION IN THEORY AND PRACTICE

By T. F. HURLEY, O.B.E.

Chief Research Engineer, Fuel Research Station, Department of Scientific and Industrial Research

A CONFERENCE on the subject of combustion was held in June of this year in the United States at Boston under the auspices of the Institution of Mechanical Engineers and the American Society of Mechanical Engineers and repeated in London in October. At each meeting the same forty papers were presented and discussed, seventeen being of British or European origin and twenty-three American.

The main idea of the conference was first to link theory and practice in the sphere of combustion by presenting the results of theoretical work to practical engineers, and secondly to provide an opportunity for practical engineers to discuss the application of theory in the field of boilers, furnaces, internal combustion engines and gas turbines. On the whole, this theme was followed and was not lost to view in the mass of useful information of a practical nature which was also presented in the papers and discussed in both Boston and London.

For convenience of discussion, the conference was divided into six sessions, the first of which dealt with the chemistry and physics of combustion from the fundamental aspect and included an American paper on the appraisal of combustion research. This paper reviewed the history of the development of the art of combustion in a comprehensive manner, and the authors' reflexions in relation to the theme of the conference obviously had a marked influence upon the views which were expressed during the discussion.

The second, third, fourth and fifth sessions were concerned with papers on boilers, industrial furnaces, internal combustion engines and gas turbines, respectively. They were mainly, though not entirely, of a practical nature and dealt with such subjects as fuels of all types, the design of equipment, operating difficulties and experiences, and instrumentation.

The sixth and final session was used to summarize the previous five and was the only one in which the conference was divided into sections for the simultaneous discussion of different groups of papers. The fundamental papers were discussed in London, but not in Boston.

It was suggested in the general papers and generally agreed in the discussion that, in the field of combustion, basic theory and practice are far apart: the practical engineer has developed his full-scale equipment and methods empirically, as a result of experience rather than by the application of scientific data. When in difficulties he may call in the chemist or the physicist to explain new phenomena which he has encountered; but the function of the scientist should be to predict as well as to explain.

Various explanations were put forward: one being that through over-specialization the engineer and the scientist not only see the same thing from different angles but also speak different languages. The engineer should therefore learn to state his problem in a manner which would be understood by the scientist, while the latter should present his results in such a way that the engineer can readily see how to apply them in practice. Some authors and speakers advocated the use of middlemen or interpreters who could speak both languages, while others thought that, whenever possible, both large- and small-scale research and development should be carried out jointly by teams comprising, in the ideal case, engineers, chemists, physicists and mathematicians.

From a different aspect a minority pointed out that the chemistry of combustion is extremely complex, and the engineer is always under pressure to adapt plant quickly to suit new conditions. He may have only a limited knowledge of the details of the combustion mechanism but, nevertheless, especially in the older fields of application, he has ample knowledge of the conditions necessary to obtain, and maintain, a very high standard of thermal efficiency, and he has amply proved his ability to apply his knowledge.

Many of the papers, taken from all sections of the conference, amply demonstrate that in most practical applications combustion, in itself, does not present a major problem. In some cases the type of fuel used and the design of the combustion equipment are decided by the size of the plant, in some by maintenance problems or ease of control, and, in nearly all, by economic considerations. In each session emphasis was placed on the effects of impurities in the fuel, which are so important that combustion problems usually become apparent only when some such effect as temperature accentuates the difficulties caused by the presence of harmful elements such as sodium, sulphur or vanadium. In boilers the process of combustion is subordinate to considerations of heat transfer and the avoidance of bonded and other external deposits; in furnaces the life of the roof is all-important; in internal combustion engines the use of residual oils has brought up problems of abrasion and corrosion, which were discussed in detail; and in industrial gas turbines, although combustion problems are more important than in some other fields, the effect of impurities such as vanadium in residual oil is receiving much attention.

Although in the past the art of combustion may have developed more as a result of experience than by the application of fundamental data, the high rates of reaction and of heat-release which are demanded when burning fuel in the newer types of equipment, such as gas turbines and ram jets, bring much nearer the time when performance will be limited by the basic mechanism of the combustion process. Possibly for this reason great interest was shown in an American paper describing experiments to determine the maximum heat-release to be obtained by burning liquid hydrocarbons and to observe the conditions which limit reaction-rates. In these experiments it was found that, under certain specified conditions, the maximum heat-release was $8{\cdot}0 \times 10^{8}$ B.Th.U. per cu. ft. per hr. per $(\text{atm.})^{1{\cdot}8}$, and that in the final stages of combustion the oxidation of carbon monoxide was the slow controlling step.

For various practical reasons the maximum heat-release obtained in these experiments is more than ten thousand times that employed in most modern water-tube boilers; but it was pointed out that heat-releases of the same order occur intermittently in internal combustion engines and a figure of several million B.Th.U. per cu. ft. per hr. was quoted for continuous combustion in gas turbines. The conclusion that the oxidation of carbon monoxide limits the maximum heat-release is consistent with British experiments showing that the combustion of carbon monoxide is inhibited by the presence of methane. It may also be in line with a statement that in the gas turbine most of the heat-release takes place in about one-third of the space used for combustion, the remainder being used for the combustion of hydrogen and carbon monoxide.

It must not be thought that, even with the older methods of combustion, progress has been made without the use of extensive research or without employing scientific methods of investigation. Thus some scientists would not regard work carried out on combustion under the rapidly changing conditions within the cylinder of an internal combustion engine as fundamental; but one paper described experiments in which the scientific method is used *inter alia* to examine the flame stability in an internal combustion engine by means of new electronic measuring devices. Similarly, much use is made of models to examine the influence of aerodynamic flow upon the combustion process in plant as divergent in construction as the open-hearth furnace and the gas turbine.

Mention may also be made of some of the other examples of applied research on combustion which were discussed at the conference. The high temperatures encountered in modern small-sized combustion chambers and the extended use of automatic control in the larger sizes have resulted in the development of many new measuring instruments. The radiation from the flames of solid, liquid and gaseous fuels is being studied by an international committee and, with each type of fuel, attempts are being made to correlate radiation with the progress of combustion. The chemical and physical properties of the ashes in various types of fuel are being studied intensely, not only with the object of reducing deposits on metal surfaces but also because of their limiting effect upon combustion conditions at high rates of heat-release. Experimental work is proceeding on the use of additives to influence the actual combustion process, as well as to reduce the effect of impurities upon deposits and upon wear and tear. Completeness of combustion is also being controlled to prevent deposits. As a final example, studies of aerodynamic flow in various types of combustion chamber are of outstanding interest on account of the influence of the flow pattern upon the conditions controlling combustion at any particular point and at any particular time.

Considering the complete conference in relation to its central theme, it would seem that the practical engineer has developed combustion techniques which have served their immediate purpose and which, in the past, have been good enough to make the actual process of combustion a minor problem. More recently, he has found it necessary to carry out intensive experimental work on closely associated phenomena; but he has not, so far, made much use of the fundamental chemistry and physics of the combustion mechanism. The conference clearly deplored this fact and supported the view that the time has arrived to take positive action to close the gap between theory and practice.

# THE SCIENTIFIC STUDY OF PLANTS*

By Prof. H. E. STREET
University College of Swansea

THE Department of Biology of University College, Swansea, was founded in 1921 under the direction of Dr. Florence A. Mockeridge; in 1936 she was elected its first professor of botany. Now the College is establishing separate Departments of Botany and Zoology and building new biological laboratories. The pioneer biologists at Swansea have faced, in some measure, that resistance which their subject has encountered at many points during its history; a resistance which arises because its impact on our dogmas and ways of life is more direct and profound than that of any other branch of science. There exists a widespread lack of understanding of the nature and importance of contemporary botany. It is therefore appropriate that I should endeavour to trace, in very broad outline, some of the main currents of its historical development.

## Systematic Botany and the Concept of Evolution

Knowledge of the usefulness of plants is as old as man himself. It was not, however, until the rise of the Greek and Roman civilizations, and then primarily in connexion with the identification of medicinal plants, that systematic and detailed descriptions of plants were written down. From work of this kind originated the "Herbal" of Dioscorides, produced in the first century A.D.

The Dark Ages intervened between the fall of Rome and the Renaissance. Then came a renewal of interest in the form of living things as exemplified by the paintings of Botticelli and the drawings of Leonardo da Vinci, by the reproductions of the texts of the Ancients, by the publication of the sixteenth-century herbals, by the anatomical studies of Harvey, and by the founding of learned societies like the Royal Society. It was at this time that botanic (physic) gardens were established in the ancient universities of Europe, and that explorers first brought to Europe many of the food plants we know to-day.

Stimulated by Bacon's dictum that the essential first step for scientific progress is the accumulation of facts, and aided by Boyle's introduction (1663) of alcohol as a preservative, there arose during the eighteenth century a group of naturalists which included Tournefort in France and John Ray in Cambridgeshire. They not only collected and described plants, but also sought to classify them into species, genera and families. They recognized not only distinct species (a unit introduced by Aristotle) but also resemblances and affinities between them. This work formed the basis for the "Systema Naturae" of Linnaeus, first published in 1735; a work which exercised a very powerful influence. Botanists assiduously sought new genera and species. They came to be esteemed within their own circle in proportion to the number of flowering plants the characters of which they knew by heart.

---

* Substance of an inaugural lecture delivered on October 27 at the University College of Swansea.

This static eighteenth-century botany, by stimulating the search for new species, brought about its own eclipse. Botanists travelled in the ships of Cook and Flinders and in the nineteenth-century voyages of scientific exploration. Knowledge of the living world grew rapidly and excited great interest. Geology developed the concepts of palæontology, making possible the study of fossil plants initiated by Robert Brown (1851). The concept of species as immutable units each dating back to an act of special creation became suspect. The similarities between species, particularly the basic similarity of structure among the warm-blooded animals, suggested a common ancestry. Fossil organisms were clearly related to, but quite distinct from, living species. Domestic animals and cultivated plants were known to have arisen by human selection of the progeny of their wild ancestors. In the writings of Buffon, Erasmus Darwin and Lamarck, species were regarded as undergoing continuous change, the bewildering variety of living organisms as having arisen from a smaller number of ancestral types and as now undergoing change into the organisms of the future. The situation awaited the synthesis achieved by A. R. Wallace and by Charles Darwin, whose "Origin of Species by Means of Natural Selection" was published in 1859.

Darwin had set forth the immense weight of evidence for the hypothesis that the diverse forms of life are of common descent. Strongly influenced by Malthus, he explained the process of change by postulating that natural variations were inherited and selected in a "struggle for existence". Darwinism and the evolutionary contention of Spencer that the direction of change had been such as to produce higher from lower forms of life became synonymous in men's minds and found wide acceptance and able protagonists.

This concept of organic evolution played an important part in the ferment of scientific ideas which characterized the second half of the nineteenth century. The challenge of Darwinism was, however, not fully understood by contemporary biologists. The systematists saw in it a justification for their work; they embroidered and extended the systems of classification, which now seemed to reveal the evolutionary sequences of the past; there arose a veritable forest of geneological trees. The spirit of the Darwinian period from 1860 until 1900 directed attention away from a really critical examination of the nature and extent of natural variation, and of the mechanism of evolutionary change.

## The Study of Cells and of Heredity

To understand how the scientific study of plants was to move forward, it is necessary to go back to the publication in 1665 of the "Micrographia" of Robert Hooke, to his "new invisible world" of the minute structure of plants revealed by the microscope, to the discovery of "cells". This was quickly followed by the work of other seventeenth-century microscopists like Malpighi and Grew, who showed that the stems, roots, leaves and flowers of plants are compounded of many different kinds of cells arranged in patterns of tissues. Further progress, however, had to await the development during the nineteenth century of more powerful microscopes. 1831 saw Robert Brown's description of the nucleus, and 1838 Schleiden's description of the cell substance (cytoplasm) in which the nucleus was always embedded. These together constitute protoplasm, the living substance of the cell. The enclosing cell wall which alone had been observed by the seventeenth-century microscopists was not the cell as we now visualize it, but simply the envelope of structural material secreted around it by protoplasmic activity.

By 1878 Abbe microscopes, with achromatic lenses, were being manufactured and distributed by Zeiss of Jena; they foreshadowed in all essentials the microscopes of to-day. By 1843 certain one-celled plants had been observed undergoing fission into two daughter cells. In 1875 Eduard Strasburger, using an improved microscope and basic aniline dyes as nuclear stains, was able to give the first detailed description of this process of cell division, showing it to be a process led and controlled by division of the nucleus. Preparatory to nuclear division, there appeared in the nucleus minute, deeply staining (chromatin-rich) threads, the chromosomes, constant in number and form in the nuclei of each plant species. During nuclear division these chromosomes underwent a precise longitudinal division so that each daughter nucleus received its proper chromosome complement; the formation of daughter nuclei was followed by division of the cell. Evidence accumulated that the chromosomes were permanent structures the staining properties of which varied with the state of the nucleus.

The new microscopes also made possible study of the process of sexual reproduction at the cellular level. In 1855 Pringsheim introduced his observations thus: "with regard to the manner in which the (sexual) organs participate *materially* in the act of impregnation and even as regards the necessity for their co-operation, there are but vague surmises". Then he proceeded to describe accurately the act of fertilization in the alga *Vaucheria*, thereby demonstrating for the first time that the subsequent development of the female cell into a new plant was not initiated by some mysterious male essence—the "*aura seminalis*" of Aristotle—but by a fusion of the sex cells. This was followed, in 1887, by Beneden's demonstration that in *Ascaris* the essential feature of fertilization is a fusion of the sex nuclei, each with the haploid chromosome number, to give a fusion nucleus containing one set of chromosomes of paternal and one of maternal origin. Preparatory to the formation of sex cells the haploid number was restored by a special reduction division, first observed in plants, again by Strasburger (1894). In this, corresponding chromosomes paired off and then separated to give haploid nuclei each containing some paternal and some maternal chromosomes. These researches pointed to the chromosomes as the physical agents of heredity. Full recognition of their significance came, however, only after botanists and zoologists, labouring to interpret the results of controlled breeding experiments, had formulated hypothetical concepts which described, at first unwittingly, and then with increasing consciousness, the nature and behaviour of the chromosomes; they had established the science of cytogenetics.

The breeding experiments of Mendel were begun in 1857, published in 1865, and then completely neglected until confirmed and acknowledged in 1900. First Mendel had studied the inheritance of single recognizable characters, for example, average height, when 'dwarf' and 'tall' varieties of peas were crossed and the hybrids selfed. To explain his results, he had to postulate that the expression of the character was controlled by a pair of determinants (in 1909 termed 'genes' by Johannsen), one derived from each parent, that in the zygote the expression of one of these factors was dominant over the other (the 'tall' gene was dominant), and that the maternal and paternal members of the gene pair suffered random distribution to the sex cells formed in preparation for the next generation. Mendel had then extended his work to study simultaneously the inheritance of two characters and concluded that the genes for separate characters were inherited quite independently.

Subsequent work, particularly with the fruit-fly, *Drosophila*, initiated in 1909 by Morgan in Columbia University, extended and modified Mendel's findings. Characters were not inherited independently but in 'linkage groups'; only characters from different groups behaved in a typical Mendelian manner. The number of linkage groups corresponded with the haploid number of chromosomes. Linkage of genes was, however, not absolute; if the genes of the linkage group were on the same chromosome, then there occurred an interchange or 'crossing-over' of genes between paired chromosomes during the reduction division—this was the genetic significance of the 'chiasmata' observed in reduction division. 'Crossing-over' frequencies between genes could only be explained by postulating that the genes are arranged in a linear series along the chromosomes; just as are the chromatin granules of the chromosome threads. The visible structural units of the chromosomes were either genes or were the loci of genes, themselves still smaller material entities. Thus arose the 'theory of the gene', from which has stemmed a deeper understanding of the twin problems of the variability within species and of their change into new species during evolution.

Darwin had postulated that evolution was a process of gradual change, the cumulative effect of successive small variations over many generations. Hugo de Vries, like others before him, was, however, convinced that series of individuals grading from one species into another, such as would be expected from Darwin's hypothesis, are in Nature conspicuous by their absence. In 1886, examining a colony of the American evening primrose, he found variants which on selfing gave rise to quite new and true-breeding forms. Here it seemed was a species disintegrating, suddenly not gradually, to use de Vries's term, by 'mutation'. Similarly, Johannsen (1913), although quite unable to alter gradually the mean seed-weight of beans by always selecting and replanting the heaviest or the lightest seed, encountered two cases of mutation in which the mean seed-weights suddenly changed to new and persistent values. These mutations were apparently quite unrelated in direction or extent to environmental influences. Their discovery, combined with the recognition that heredity operates through special sex cells set aside early in development, formed the starting point for the now generally accepted view that evolution has proceeded by naturally occurring mutation. These sudden changes are quite unrelated to characters 'acquired' during the development of the organism. They are subjected to natural selection or rejection, and, since many are unfavourable, there is a preponderance of rejection.

The rapid accumulation of genetic data which followed the rediscovery of Mendel's work not only exposed the phenomena of 'linkage' and 'crossing-over', but also that of gene interaction. Gene interaction, together with the independent inheritance of 'linkage groups' and their fragmentation by 'crossing-over', showed that inherited variation could arise by a reshuffling, during reduction division, of a fixed gene population. Mutations, the changes important in evolution, were, by contrast, shown to involve either quantitative or qualitative change in the gene population. One kind of mutation arose from breakdowns in chromosome behaviour; their frequency could be speeded up by agents like colchicine and mustard gas. Such chromosome mutations involved deletions or duplications of chromosomes or of chromosome segments; sometimes duplications of whole sets of chromosomes (polyploidy). The second kind, gene mutations, involved radical changes in individual genes. These also occurred naturally with a very low frequency; many mutations of this kind have been induced by X-rays, gamma-rays and other radiations.

It thus became possible to explain at the chromosome-level the concept of species, the nature of natural variation within species and the mechanism of evolutionary change.

## Plant Physiology and Biochemistry

It is necessary now to consider the development of a further, and again quite different, level of approach to biological problems.

The seventeenth-century microscopists, observing the development in organic fluids of innumerable moving microscopic organisms, concluded that they had demonstrated the 'spontaneous generation' of life as postulated by Aristotle. Pasteur and Tyndall showed that, in all cases of this kind, the organisms had reached the suitable source of food and moisture by being carried via the air. Their researches also proved that natural fermentations were always associated with living organisms and were not chemical processes in the sense visualized by Liebig. The foundations were laid for the demonstration that infectious diseases were caused by micro-organisms capable of surviving a period of separation from their stricken hosts. Infective fluids could be sterilized either by heat or by removal of the micro-organisms by passage through bacteria-proof filters.

However, in 1892 and again in 1896, it was shown that the juice of tobacco plants infected with 'mosaic' could not be freed from its infectivity by filtration. This observation was a landmark in the discovery of viruses. Further, the infective agent causing the 'mosaic' disease, the tobacco mosaic virus, when isolated by chemical procedures, consisted entirely of ribonucleoprotein. Here was a chemical entity capable of causing an infectious plant disease, requiring suitable living host cells for its duplication, something non-living when isolated, living when introduced into the cytoplasm of the host, in some of its properties an organism, in others a large molecule.

Here we have raised in an acute form the transition from a chemical to a biological level of organization.

In studying life as a material system, as a unique state of matter, we attempt to utilize the techniques of experimental science, particularly those of chemistry and physics, and to extend the concepts of the physical sciences to aid in the interpretation of a higher level of organization. Such studies have revealed life as a dynamic system, a system of happenings, of physical and chemical processes proceeding—have established the science of physiology.

While eighteenth-century botany was preoccupied with systematics, physiology was mainly a speculative occupation of physicians. Outstanding, however, was Stephan Hales, who, working in his vicarage garden at Teddington, sought by experiments to explain the action of living plants on the basis of known physical forces. In 1727 he published "Vegetable Staticks", the foundation work of plant physiology.

By the second half of the eighteenth century, men of many persuasions were studying the nature of air and the effects of plant and animal life on its composition. Priestley, Ingen-Housz and de Saussure were conducting experiments which in aggregate demonstrated that at all times plants and animals are absorbing oxygen and exhaling carbon dioxide (performing respiration); and that in addition green plants have the unique power, in sunlight, to effect photosynthesis. Photosynthesis involved the uptake of carbon dioxide, the evolution of oxygen and the synthesis of organic matter.

These and many other pioneer researches in plant physiology were set forth with great clarity in 1865 by Julius Sachs in his "Physiology of Plants". Here we find respiration described as the process which effects a continuous liberation of energy by the oxidation of the organic food reserves of the cell and the concept that this constant energy supply is essential for the maintenance and growth of protoplasm. Here, in an account illuminated by his own researches, Sachs sets out the general nature of photosynthesis, identifies chlorophyll as the essential catalyst, describes starch as the first visible product and recognizes this as a complex compound capable of yielding respiratory energy or acting as the starting point for the synthesis of other protoplasmic constituents.

The forceful writings of Liebig, particularly the publication in 1840 of his "Chemistry in its Application to Agriculture and Physiology", had led to a wide acceptance of the inorganic theory of plant nutrition, that the essential nutrients required by plants are obtained either from the soil or from the air in inorganic form. Liebig had shown ammonium salts to act as effective sources of nitrogen for plant growth. Boussingault in 1838 had similarly demonstrated the manurial properties of Chilean nitrate, first introduced into Europe in 1820. Boussingault's use of washed sand as a growth medium and the development of water-culture techniques by Sachs and Knop made it possible to identify the elements essential for plant growth, work which ultimately led to the recognition and effective treatment of the important deficiency diseases of crops.

The plant physiologist is, however, not only concerned to define what nutrients are essential but also seeks to trace the chemical changes which they undergo in the chemical reactions of the cell; to trace their role in metabolism. At first, studies of this kind were approached by indirect means, and knowledge of cellular mechanisms was purely circumstantial. However, in 1897, Buchner performed an experiment initiating the science of biochemistry. He obtained from disintegrated yeast cells a clear aqueous solution capable of effecting the alcoholic fermentation of sugar. The biological and chemical theories of fermentation so keenly argued by Pasteur and Liebig had both been vindicated.

The yeast juice of Buchner was afterwards shown to contain a mixture of soluble ferments or enzymes, each responsible for catalysing one of the sequence of linked reactions involved in sugar fermentation. With the progress of biochemical studies it became apparent that enzymes are extremely active, specific and relatively unstable catalysts, and that all, or almost all, the chemical reactions of cells are under enzyme control. When these enzymes were separated and purified, they were found to be either proteins or proteins associated with units of smaller molecular weight, the co-enzymes (some of the latter are now known to be identical with the vitamins). Protoplasm clearly contained several kinds of proteins, reserve proteins, structural proteins responsible for its molecular framework and colloidal properties, and, in small amounts, several hundred specific enzyme proteins controlling cell metabolism.

The discovery of a further kind of protein and a brief discussion of its special role in living cells will serve to illustrate one important way in which plant physiology has deepened our understanding of the major botanical problems the development of which we have followed. Miescher in 1868 isolated the nuclei from pus cells and demonstrated that they contained an unusual phosphorus compound, a new kind of protein, a nucleoprotein. This we now describe as deoxyribonucleoprotein, a compound formed by combination between basic proteins and deoxyribonucleic acid (DNA).

Using modern techniques, it has been possible to study quantitatively the distribution of nucleic acids within cells and to show the universal presence not only of DNA, but also of a second kind of nucleic acid, ribonucleic acid (RNA), also associated with basic protein. From such studies we know that DNA-protein is concentrated in the chromosomes, coinciding in distribution with the chromatin of the cytologists. Nuclei also contain RNA-protein, concentrated in separate nuclear regions and apparently implemented in the synthesis of the DNA-protein.

Nucleic acids were at first considered to be strictly nuclear constituents. The cytoplasm has now been shown to contain cytoplasmic particles, reproducing by fission, rich in RNA-protein, and uniquely rich in enzymes.

Cytoplasm cannot persist in the absence of the nucleus, nor are isolated nuclei self-perpetuating. The two are interdependent. This suggests that the nucleus is dependent upon cytoplasm for organic and inorganic nutrients, and that the nucleus controls cytoplasmic activity by sending out into it 'messengers', some of which it seems from recent genetical work are involved in the origin of persistent and self-duplicating plasmagenes. Viruses may represent plasmagenes which have gained access to and proved capable of multiplying in a foreign cytoplasm and thereby caused a pathological disturbance of metabolism inducing disease symptoms.

The chromatin granules of the chromosomes, carriers of the nuclear genes, cytoplasmic particles, apparently carriers of plasmagenes and other less stable 'gene products', and the viruses are all units capable of self-duplication with retention of their specific properties. They are all nucleoproteins or are rich in nucleoprotein. Nuclear genes and viruses show mutation. Nucleoproteins confer upon these genetic units their specific properties ; nucleoprotein molecules in the environment of the living cell can exactly replicate themselves. We are led to conclude that the massive molecules of nucleoprotein can exist in, at least, as many specific configurations as there are genetic units, that mutations arise from sudden and stabilized changes in their molecular configuration, and that evolution depends upon the structural variations achieved in these special molecules.

The evidence that the RNA-proteins of the nucleus are concerned with the synthesis of chromosome proteins suggests that the RNA-proteins of the cytoplasmic particles may be responsible for the synthesis of enzymes ; that genes may control metabolism by controlling, through the medium of their 'messengers', the establishment and activity, in the cytoplasm, of the nucleoprotein centres of enzyme synthesis. Many mutations would then be expected to result in derangements of the delicately adjusted and interlocked reaction chains of cell metabolism. This is the thesis behind the studies in biochemical genetics initiated in 1940 by Beadle and Tatum at Stanford University and afterwards developed in many laboratories. Mutants of fungi and bacteria induced by X-rays have been isolated which have more elaborate and definable nutritive requirements than the parent 'wild' strains. Using appropriate X-ray dosages, many of the mutants have an induced requirement for a single essential metabolite. The induced requirement arises from the breakdown of a single identifiable reaction in cell metabolism. In a number of cases the enzyme controlling the critical step is known and the mutant has been shown to differ from the 'wild' strain in lacking the operative enzyme. Where the micro-organism reproduces sexually, breeding experiments have revealed that the mutants lacking a single enzyme are single-gene mutations. The nuclear genes act, in such cases, by controlling the synthesis of single enzymes. Such gene control could be responsible for the physiological and morphological characters which are the concern of the plant-breeder.

Study of the physiology and biochemistry of nucleoproteins has therefore contributed to our knowledge of the chemical nature of genes and of their mechanism of action, and thereby deepened our understanding of heredity and natural variation.

Contemporary botany has made great contributions not only to the material welfare of mankind, but also to our understanding of life. It is now raising questions enlivening and taxing not only the biological but also the physical sciences. It is in the borderlands between these sciences that, in the immediate future, we may expect the most important discoveries. This poses important problems in the training of biologists and in the development of research.

---

# IS THE GENE A PRIME MOVER?

By Prof. CARL C. LINDEGREN

Biological Research Laboratory, Southern Illinois University, Carbondale

RECENT advances in understanding the chemical structure of deoxyribonucleic acid[1] together with evidence[2] of its capacity to mediate the transfer of genes from cell to cell has led to the belief that the secret of life lies in this nucleic acid. Such optimism has its basis in the idea that the gene is the fundamental, 'self-perpetuating', *primary*, living particle[3].

The possibility that the gene is a terminal or recent addition to the cell has not been sufficiently considered. There can be no question that the chromosomes and their genes are essential components of living matter as we know it to-day ; but this does not prove that they are *primary* components of living material. Electrical devices are essential components of the organism which we call Chicago, and there is little doubt that, without electrical devices, Chicago would perish and yield its place to some competing metropolis not similarly handicapped. It is equally clear that such devices are not primary components and that Chicago existed as an organism for a long time without them, although they now play a vital part in the city's life.

Numerous critical experiments have shown that extra-chromosomal autonomous structures are present in the cell. (1) Michaelis[4] proved (by back-crossing interspecific hybrids of *Epilobia* to the male parent) that replacing all the chromosomes of one species by those of another did not completely convert the recipient species. (2) Renner[5] has shown that the chloroplasts (which are free of deoxyribonucleic acid) are autonomous structures. (3) Harder[6] showed that the removal of one nucleus from a dikaryon of a hymenomycete (which contains the cytoplasm from both gametes) produces a surviving cell (with nucleus *A* in a mixture of both *A* and *B* cytoplasms) that is permanently different from the parent containing nucleus *A* in *A* cytoplasm—thus establishing the autonomy of *B* cytoplasm.

Now that the gene is allegedly a pure chemical compound, it seems difficult, if not impossible, to ascribe the mysterious capacity for 'self-reproduction' to it. It seems obvious that no chemical possesses an autonomous capacity for reproducing itself, for it must depend upon the environment for its components and the synthesis must be mediated by an enzyme. Self-duplication reduces to a mechanism whereby the enzymes controlling the synthesis and the structure which is synthesized are intimately associated. Many components of the cell other than the chromosomes appear to possess an autonomy which operates at this level. It is as inconceivable that a cell could survive without a plasma membrane as that it could survive without genes. The secret of life is not to be found in the structure of any given chemical, but in the organization and association which make the whole cell capable of producing all the components necessary to the synthesis of all the cellular organelles when placed in an adequate milieu[7]. This statement does not solve the secret ; but it denies that the solution lies in the gene alone. Life may have originated by the association of a synthesizing enzyme with a protein in some circumstances (depending upon structural interrelationships) by which the protein and the enzyme were reconstituted together. The next step could be the development of a differentiated envelope for the protein mass associated with its own synthesizing enzyme. Many synergistic components may have followed, each of which facilitated the synthesis of the complex, and each of which halted all syntheses when the particular components necessary for its construction were in short supply.

The demonstration of the essential nature of the gene depends upon the fact that deletion of a gene produces a lethal result. It is clear from the previous discussion that this fact does not prove that the gene is a primary component of the cell. Actually, one would expect co-ordinating and regulating functions to be superimposed late in the evolution of the cell. Many synthetic steps might involve minute amounts of regulatory materials which were required to act upon a specific substrate for a specific purpose. The critical value of the gene may depend on such a device. The control of adaptive enzymes by genes suggests that such trivial but occasionally valuable activities are controlled by genes. During the early phases of the development of gene theory it was proposed that genes differentiated specific or varietal characters while cytoplasm differentiated characteristics distinguishing genera or phyla. One ordinarily thinks of controlling, supervising and co-ordinating functions as relatively recent rather than primary activities of organizations whether they be cities or countries or cultures; genes may be recent agents in the origin of life carrying on functions similar to those of the electrical devices in a city such as Chicago.

There is a specific characteristic which is not consistent with the view that genes are composed of deoxyribonucleic acid. Evidence[8] concerning the gene controlling galactose-fermentation in *Saccharomyces* has been interpreted to indicate that genes may be plastic, since the substrate for a gene controlling the production of an adaptive enzyme is itself a mutagen controlling the mutation of the gene from a non-functional to a functional state. Similar instances have been encountered in studying the genes controlling carbohydrate fermentation in *Saccharomyces*. Rather than a rigid structure such as deoxyribonucleic acid, the genes themselves may be plastic materials attached to deoxyribonucleic acid. Lindegren[9] suggested that the rigidity of the chromosome made it an ideal site for assembly-line synthesis of gene-products, and the brilliant researches of Demerec (personal communication) have revealed that such assembly-line syntheses actually do occur. There is evidence[10] that gene products may not always be synthesized at the locus of the gene, and this suggestion leads one to suppose that the fibrous nature of the chromosome is exploited as a means of communication and co-ordination, and that the basic functions of deoxyribonucleic acid are to hold the plastic material of the gene in place and to transmit information from it to a functioning cell centre.

This work was supported by grants from the Illinois Division of the American Cancer Society and the U.S. Atomic Energy Commission, *AT*(11-1)176.

# OBITUARIES

## Sir Arthur Tansley, F.R.S.

Sir Arthur Tansley, who died on November 25, must be ranked as one of the makers of British botany. During his long and active life he exerted a profound influence on the development of the science, and on the attitude of botanists towards the study of the plant world.

Tansley was born in 1871, educated at Highgate School, University College London, and Trinity College, Cambridge. At University College he came under that inspiring personality F. W. Oliver, and at Cambridge he was influenced by Francis Darwin, Seward, and F. F. Blackman, who for many years was one of his closest friends. After taking a first class in Part II of the Natural Sciences Tripos at Cambridge, he returned to London as Quain Student at University College, later becoming demonstrator and assistant professor there. At this period he was much interested in evolutionary problems, then so much in the minds of botanists; he worked on the anatomy of ferns and on seedling structure. In 1902 he embarked on the bold venture of founding a new botanical periodical, *The New Phytologist*, which was to be "a medium of easy communication between British Botanists". He realized that this was a hazardous experiment, and at first he acted both as editor and publisher. The experiment proved completely successful, and in the thirty years during which he was editor the journal became one of the principal botanical publications in the world. It frequently contained important contributions by the editor, such as his "Lectures on the Evolution of the Filicinean Vascular System". It was important, too, in promoting an integration of the various branches of botany hitherto regarded as distinct.

In 1903 he married Edith Chick, his successor in the Quain studentship, and three years later he returned to Cambridge as University lecturer. He settled in a beautiful home at Grantchester which became a centre for botanists young and old. His lectures presented fresh points of view, especially those on ecology, at that time a new subject in Britain. Tansley had begun this study in London with Oliver, and he became an active member of the Committee for the Study of British Vegetation. The work of this Committee, and the articles in *The New Phytologist* on "Vegetation at Home and Abroad", did much to spread an interest in plant ecology which brought together taxonomists, physiologists and anatomists. In 1911 he organized the first International Phytogeographical Excursion to the British Isles. For this he produced a noteworthy book, "Types of British Vegetation". Two years later he took a leading part in the formation of the British Ecological Society, of which he was the first president; during 1916–37 he edited the Society's *Journal of Ecology*.

During the First World War Tansley undertook work in the Ministry of Munitions, and afterwards he spent a period in Vienna with Prof. Freud. This resulted in his well-known book "The New Psychology", which spread a knowledge of Freud's theories widely in Britain. Afterwards his mind became much occupied with the teaching of botany in schools, and in 1922 he produced an admirable text-book, "Elements of Plant Biology", which had a far-reaching influence. In 1923 he was president of Section K (Botany) of the British Association, and delivered a very stimulating address on the position of botany at that time, in which he called for a new outlook in the study of plants. In the same year he resigned his university post at Cambridge and for a few years occupied himself with research and writing. His important work with T. F. Chipp on "Aims and Methods in the Study of Vegetation", and his "Practical Plant Ecology" date from this period.

A new phase in his career came in 1927 with his election as Sherardian professor of botany and fellow of Magdalen College at Oxford. Here he did much to stimulate and reorganize the study of botany. He collected around him a group of able young men and restored the old prestige of the department. He did much to prepare the way for the provision of a new building, though this was not constructed until after the Second World War.

On his retirement from Oxford in 1937 he devoted himself mainly to the completion of his monumental work, "The British Islands and their Vegetation", in which his own wide knowledge and the labours of British ecologists over some thirty years were epitomized. This fine volume, written in the lucid style which characterized all his works, will long remain as a memorial to his influence and enthusiasm; and it gained for him the Gold Medal of the Linnean Society of London. But his energies were still by no means exhausted, and in 1943 he became chairman of a committee to consider nature conservation and nature reserves in post-war Britain. His book, "Our Heritage of Wild Nature", and his addresses on various occasions did much to arouse a consciousness of the value to the nation of the preservation of areas inhabited by interesting plants and animals. He took an active part in the plan for helping teachers and students of all kinds to study plants and animals in their natural habitats, becoming president of the Council for the Promotion of Field Studies; he also provided students with "An Introduction to Plant Ecology", and was joint author of "Plant Ecology and the School". His appointment as first chairman of the Nature Conservancy in 1949 was a fitting climax to his efforts for so many years.

Tansley's work was recognized by his election to the Royal Society in 1915, to an honorary fellowship at Trinity College, Cambridge, in 1944, and by the conferment of a knighthood in 1950.

He will be widely mourned as a leader and a friend.

H. HAMSHAW THOMAS

## Sir Richard Paget, Bart.

SIR RICHARD ARTHUR SURTEES PAGET died on October 23 at the age of eighty-six. He was educated at Eton and Magdalen College, Oxford. After qualifying as a barrister and becoming a member of the Inner Temple, he gave valuable services on a number of industrial panels and commissions, where his genial personal qualities fitted him well as a negotiator. The bulk of his life, however, was spent in the cause of science. He loved science and brought the scientific attitude of mind to bear upon problems in many diverse fields—thus he achieved important work and gained distinction in physics, anthropology, architecture, town planning, acoustics, linguistics, speech and several artistic crafts. He was, moreover, of an inventive turn of mind, delighting in novel and unorthodox ways of viewing things, so that it is not surprising that he anticipated by half a century some present-day developments such as the streamline motor-car.

When in 1915 Britain was faced with calamity, he was one of the first to realize the urgency of well-directed scientific research on a national scale; he acted as assistant secretary of Section II of the Admiralty Board of Invention and Research during 1915–18. Not a few of the practical investigations undertaken by the Board during the First World War were the direct result of his foresight, to which tribute was paid on more than one occasion by the late Sir William Bragg, who was in charge of experimental work for the Navy.

Mention must be made of Sir Richard's keen interest in the arts. He was an accomplished musician, being particularly adept at keyboard improvization and composition. Folk music had a great fascination for him and provided an interest which he was ultimately able to link with his later studies on speech and language. Coupled with his inventiveness was a rare manual dexterity leading to skill in scientific experimentation and many forms of practical art; for example, he excelled in the manufacture of pottery. As recently as June 1954, prior to a Friday Evening Discourse at the Royal Institution, he created intense interest by demonstrating his early models of the action of the vocal apparatus by which he could reproduce consonants and vowels, thereby simulating human speech. Though these models were connected with work done more than forty years ago, they struck the observer most forcibly at once by the elegance of their simplicity and their appropriateness for the purpose in hand. It is good to know that Sir Lawrence Bragg has now received the models for the Royal Institution Museum and will use them in his lectures from time to time.

Perhaps the most outstanding work of Sir Richard Paget was that upon speech and language. His extreme humanitarianism led him to exert himself to the full in the cause of the deaf and dumb. He put much effort into the development of a sign language for their use.

Several glowing appreciations of Sir Richard's scientific work have already appeared in the Press, both at home and overseas. All of them stress his amazing versatility, his originality of outlook, his zest for life and, above all, his great personal charm and humanity. Perhaps, in concluding, I may be permitted to introduce a personal note. When in 1938 I was faced with the task of opening the large new South-West Essex Technical College and School of Art, the extremely diverse problems involved in equipping departments of science, engineering, architecture and building, commerce, women's subjects, and not least a school of art, were just such as to appeal to Sir Richard's 'universal' mind. He gave me much practical advice and designed not a few special pieces of equipment for me. He afterwards addressed the students with great success. The building of the College organ also interested him, and at the opening recital he sketched the instrument and the organist. There must be many like myself who cherish memories of his ready, generous and expert counsel and assistance. H. Lowery

# NEWS and VIEWS

## Dr. Karl Jordan, F.R.S.: Ninety-fourth Birthday Presentation

Dr. Karl Jordan, the distinguished entomologist, was honoured on his ninety-fourth birthday by the presentation of a jubilee volume at a meeting of the Royal Entomological Society held at the Society's house in Queen's Gate, London, on December 7. The volume contains a series of essays and scientific papers by entomologists of many countries reflecting the numerous facets of Dr. Jordan's work. The essays include a biography, and reviews of Jordan's work in organizing the International Congresses of Entomology, his work for the organization of zoological nomenclature, his work on fleas, his influence on current concepts of systematics and evolution, his contributions to the systematics of Anthribid beetles and his work on the Lepidoptera. There follow a bibliography listing some 460 items written by Dr. Jordan over a period of seventy years, and twenty scientific papers. Few men can have contributed more to the science of entomology than Dr. Jordan, and it was fitting, and a sign of the high regard in which he is held throughout the world, that the jubilee volume was initiated in the United States. It was Mr. H. K. Clench, of the Carnegie Museum, Pittsburgh, who fired the enthusiasm of friends of Dr. Jordan in the United States, Canada and in Britain, and who was responsible for a large part of the work of assembling the contributions. The Royal Entomological Society of London, of which Dr. Jordan is an Honorary Fellow, undertook the publication of the volume.

## Peaceful Uses of Atomic Energy: India and the United Kingdom

The United Kingdom Atomic Energy Authority states that discussions between the United Kingdom Atomic Energy Authority and the Indian Department of Atomic Energy have led to the conclusion of an agreement which ensures that there shall be close co-operation and mutual assistance between the Authority and the Department in the promotion and development of the peaceful uses of atomic energy. The agreement provides for the Authority and the Department to arrange for members of their staffs to consult and work together on mutually agreed topics. In furtherance of this agreement, the United Kingdom Atomic Energy Authority will provide the Indian Department of Atomic Energy with enriched uranium fuel elements for a 'swimming pool' reactor now under construction at Bombay. The agreement also includes arrangements for the Authority to assist in the design and construction of a high-flux research reactor which may be built at a later date.

## Technical Education in Great Britain

Replying to questions on technical education in the House of Commons on December 13, the Prime Minister re-affirmed the Government's determination to make a big advance in technical education and said that the Minister of Education would make a further statement shortly on technical colleges. Sir Anthony Eden did not think that appointment of a committee to inquire into all aspects of scientific, technological and technical training or of a Minister for Technical Education would help. He gave no direct reply to questions regarding the position relative to the U.S.S.R., but said that last year about £4·5 million was spent on improvements in various spheres of technical education. This year £7 million is being spent and next year £9 million. No contracts for technical colleges in Britain were placed during 1946–47, but during subsequent years the figures are: 1948–49, £222,000; 1950–51, £874,000; 1952–53, £3,307,000; and last year just under £7 million.

## Sea-going Facilities for Naval Scientific Workers

Increasing facilities are being granted by the Royal Navy so that scientists, designers and others concerned with the development of new equipment for the Navy can serve afloat and study the problems of those who use their equipment. For some time naval officers have been specially appointed to naval research and development establishments in an endeavour to ensure that civilian officers fully appreciate naval problems, but it is being more and more realized that knowledge and appreciation cannot be fully acquired through the experience of others. Long periods at sea are possible only for a small proportion of those in the Royal Naval Scientific Service engaged on research, design and the production of naval equipment, but many, including draughtsmen, do visit ships for trials and inspections, even if they do not always proceed to sea. During fleet exercises a number of civil officers are embarked in various units of the fleets as observers to study the general problems of operation and weapon efficiency, and there are, of course, members of the Royal Naval Scientific Service attached to the staffs of the Commanders-in-Chief, Home Fleet and Mediterranean Fleet, as fleet scientific advisers. During recent years the amount and complexity of electronic equipment now fitted in ships have increased to such an extent that special efforts are made to enable the designers and producers of this equipment to study at sea the problems of the user and the maintenance staff. During the past eighteen months the fleets have been able to accommodate in various ships, for periods varying between a few days and four or five weeks, about one hundred civil scientific officers engaged in this sort of work; included in this number are staff representatives from Ministry of Supply Establishments, which are responsible for most of the airborne electronic equipment for the Navy, and also designers and engineers of industrial firms engaged on Admiralty work.

## Vacation Courses in Synoptic Meteorology

For the sixth year in succession, the Royal Meteorological Society, in conjunction with the Council for the Promotion of Field Studies, held in the early autumn a vacation course in elementary synoptic meteorology at the Council's field-centre at Malham Tarn. This year, however, in view of the increasing number of applications, a parallel course for sixth-form pupils was also held at the Juniper Hall Field-Centre. The course at Malham Tarn was attended by thirty-five students, mainly undergraduates, reading for degrees in mathematics, physics and geography, and the Juniper Hall course had an attendance of thirty-two. The instructors at Malham were Mr. C. D. Ovey, lecturer in geography at the University of Cambridge, and Dr. R. S. Scorer, lecturer in meteorology, Imperial College; Mr. E. J. W. Spence dealt with the construction and use of meteorological instruments. At Juniper Hall the instructors were Mr. W. D. S. McCaffery and Mr. C. E. Wallington, both of the Meteorological Office. The visiting lecturers at Malham included Prof. P. R. Crowe, University of Manchester, who discussed "Some Problems of Tropical Weather"; Dr. D. Walker, University of Cambridge, who gave a talk on palæo-ecology; and Prof. G. Manley, Bedford College, London, whose subject was "The Study of Climatic Variations". At Juniper Hall, Mr. R. E. Lacy, Building Research Station, dealt with meteorological problems in the building industry; Mr. H. Charnock, National Institute of Oceanography, explained the inter-relationship between oceanography and meteorology; Mr. R. A. McCormick, at present visiting Great Britain on an exchange basis between the U.S. Weather Bureau and the Meteorological Office, described the work of the former; Mr. D. H. Lucas, Central Electricity Authority Research Laboratories, spoke on smoke pollution; and Dr. R. M. Goody described research on the upper stratosphere. At Juniper Hall an excursion to the Meteorological Office Radiosonde Station at Crawley was arranged, and a visit was also paid to the Research Laboratories of the Central Electricity Authority at Leatherhead. An important part of the course consisted of observation work and the plotting of synoptic meteorological data. A novel feature at the Malham Tarn course was the use of a specially equipped meteorological van, kindly lent by the Department of Meteorology of the Imperial College of Science and Technology. Simultaneous observations of pilot balloons by two theodolites were made by radio-communication. As in previous years, various education authorities and the Education Department of the R.A.F. made it possible for some of the students to attend the courses, which are approved for grants in suitable cases. Similar courses will be held in 1956 at the Malham Tarn Field-Centre for undergraduates during August 22–29 and at Flatford Mill Field-Centre for sixth-form pupils during September 5–12. Early application is advisable.

## An Abnormal Smoke Belt over London

About 1 p.m. on Sunday, January 16, 1955, a belt of extreme darkness crossed the London area from north-west to south-east, causing widespread public interest and attention in the press. The belt of smoke and low cloud was about 1½ miles wide and moved at 6–18 m.p.h., taking 6–10 minutes to cross a given place. The daylight illumination as recorded at Kew Observatory (normally about 7 kilolux at this time on overcast days in January) dropped at 1.14 p.m. from 7 kilolux to a value barely distinguishable from zero. In the November issue of the *Meteorological Magazine* (p. 342), N. G. Helliwell and M. J. Blackwell describe the physical causes. The essential features were a low inversion of temperature (increase of temperature with height instead of the usual fall) beneath which smoke was trapped, and a change of wind direction associated with the eastward movement of the centre of a depression across London. The smoke was carried north-westwards, first of all by the south wind ahead of the centre to the Chilterns, and concentrated there against a front with north-easterly winds on its northern side. As the depression moved, the wind changed to north-west and brought the smoke belt back across the London area. Trajectories of the smoke are given in the paper. It was possible from observations to trace its further movement south-east to the Sussex coast. The amount of smoke pollution at the Fuel Research Station, Greenwich, increased from 0·36 mgm. m.$^{-3}$ between 1 and 1.15 p.m. to 0·7 mgm. m.$^{-3}$ during 1.45–2.45 p.m., when the extreme darkness occurred there. At Grosvenor Road the maximum pollution of 1·3 occurred earlier, and the value at the time of darkness was 0·3. During the infamous smoke fog of December 5, 1952, the pollution reached 4·5 mgm. m.$^{-3}$ at Greenwich.

## University of London

The following appointments have been made in the University of London: Dr. B. C. King, senior lecturer in the University of Glasgow, to the University chair of geology tenable at Bedford College; and Dr. K. W. Sykes, senior lecturer in the University College of Swansea, to the University chair of physical chemistry tenable at Queen Mary College. The title of reader in biochemistry in the University of London has been conferred on Dr. A. L. Greenbaum in respect of his post at University College.

## Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: D. C. P. Evans (agricultural officer, Gold Coast), senior agricultural officer, Gold Coast; J. S. Addison, J. S. Smith and M. L. Webber (conservators of forests, Federation of Malaya), conservators of forests, grade A, Federation of Malaya; A. Foggie (conservator of forests, Gold Coast), deputy chief conservator of forests, Gold Coast; F. G. Harper (senior assistant conservator of forests, Gold Coast), conservator of forests, Gold Coast; F. H. Landon (conservator of forests, Federation of Malaya), chief research officer, Federation of Malaya; D. McIntosh (conservator of forests, Northern Region, Nigeria), deputy chief conservator of forests, Northern Region, Nigeria; B. E. Webb (forest engineer, Federation of Malaya), conservator, development and utilization, Federation of Malaya; M. S. Garson (geologist, Nyasaland), geologist, Cyprus; Dr. E. R. N. Cooke (pathologist, Kenya), specialist (pathologist), Kenya; P. B. Cornwall (scientific officer, West African Cocoa Research Institute, Gold Coast), senior scientific officer, West African Cocoa Research Institute, Gold Coast; A. E. Dorman, J. F. Hart and R. W. E. Lewis (veterinary officers, Kenya), provincial veterinary officers, Kenya; K. D. S. MacOwan (deputy director of veterinary services, Kenya), director of veterinary services, Kenya; K. D. S. Baldwin, economist, Agriculture Department, Northern Region, Nigeria; J. A. Bullock, scientific officer, entomologist, Kenya; J. C. Davies, entomologist, Department of Agriculture, Uganda; F. Isherwood, scientific officer, entomologist, East Africa High Commission; W. P. Mowat, scientific officer, plant pathologist, Sarawak; N. C. Loveday, assistant conservator of forests, Tanganyika; D. R. McQueen, silviculturist, Nyasaland; M. T. Ashcroft, medical research officer, grade 2, East Africa High Commission; M. N. Henry, pathologist, grade B, Trinidad; P. D. Meers, pathologist, Nigeria; A. W. Ireland, deputy director of meteorological services, Nigeria; C. P. MacKenzie, veterinary education officer, Nigeria; S. M. Rimmer, veterinary officer, Tanganyika; D. J. Garrod, scientific officer, East African Fisheries Research Organization, East Africa High Commission; D. J. C. Orr, game ranger, Tanganyika; Dr. E. W. Russell, director, East African Agriculture and Forestry Research Organization, East Africa High Commission; E. A. Salzen, scientific officer, marine biologist, West African Fisheries Research Institute, Sierra Leone; P. D. Turner, mycologist, West African Cocoa Research Institute, Gold Coast.

## The Night Sky in January

New moon occurs on Jan. 13d. 03h. 01m., u.t., and full moon on Jan. 27d. 14h. 4m. The following conjunctions with the Moon take place: Jan. 1d. 23h., Jupiter 7° N.; Jan. 8d. 11h., Mars 2° N.; Jan. 8d. 18h., Saturn 4° N.; Jan. 14d. 22h., Mercury 4° S.; Jan. 16d. 09h., Venus 7° S.; Jan. 29d. 06h., Jupiter 6° N. In addition to these conjunctions with the Moon, Mars is in conjunction with Saturn on Jan. 14d. 21h., Mars 1·6° S., and with Antares on Jan. 26d. 21h., Mars 5° N.; also, Jupiter is in conjunction with Regulus on Jan. 27d. 19h., Jupiter 0·7° N. Mercury sets at 17h., 17h. 55m. and 16h. 10m. on January 1, 15 and 31, respectively. Its stellar magnitude varies from −0·7 to 2·1, and the visible portion of its illuminated disk from 0·864 to 0·046 during the month; it will not be so conspicuous towards the end of the month in spite of the fact that it attains a greater altitude. Venus sets at 18h. 25m., 19h. 10m. and 20h. on January 1, 15 and 31, respectively. Its stellar magnitude varies from −3·4 to −3·5 and the visible portion of its illuminated disk from 0·868 to 0·796, its distance from the Earth varying between 129 to 113 million miles. Mars rises shortly after 4h. during January and has an eastward motion through Libra and Scorpius. Its stellar magnitude varies from 1·7 to 1·5, and its distance from the Earth from 195 to 171 million miles. Jupiter rises at 20h. 40m., 19h. 35m. and 18h. 20m. at the beginning, middle and end of the month, respectively, its stellar magnitude varying between −1·9 and −2·0, owing to its distance from the Earth decreasing from 437 to 411 million miles; its westward motion in Leo can be observed by comparing its positions with reference to Regulus during the month. Saturn rises at 4h. 50m., 4h. and 3h. on January 1, 15 and 31, respectively, and has an easterly motion in Scorpius; but it lies rather low for good observation in the British Isles. It is fairly close to β Scorpii during the month, and its stellar magnitude remains 0·8. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Jan. 1d. 02h. 07·4m., ω Leo. *m* (*R*); Jan. 16d. 18h. 32·5m., 51 Aqr. *m* (*D*); Jan. 31d. 06h. 39·0m., 13 *B* Vir. (*R*), *R* and *D* referring to reappearance and disappearance, respectively. The Earth is in perihelion on Jan. 2d. 13h. The Quadrantid meteors are active on the first few days of January, but moonlight will interfere with their observation.

## Announcements

Mr. J. P. Doncaster, at present in charge of the collections of aphids and allied groups of insects in the Department of Entomology of the British Museum (Natural History), has been appointed a deputy keeper of the Department.

Dr. R. L. Mitchell, head of the Department of Spectrochemistry, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, has been appointed deputy director of the Institute, and Dr. E. G. Williams head of the Department of Soil Fertility.

Mr. W. T. O'Dea, keeper of the Department of Aeronautics and Sailing Ships in the Science Museum, London, has been released for three months to undertake an exploratory mission for Unesco as technical assistance expert in Ceylon under the Colombo plan. He will advise the Government of Ceylon on the establishment of a science museum at Colombo and will call at New Delhi on his return journey to discuss with representatives of the Government of India their proposals for science museums in four widely separated localities.

The Scientific Instrument Manufacturers' Association is arranging to hold a permanent exhibition of instruments made by member firms at its headquarters at 20 Queen Anne Street, London, W.1. The exhibition, which will be opened on February 9, is not intended to be public, but it will be open to anyone interested in using scientific instruments.

A David Anderson-Berry Silver-Gilt Medal and a sum of about £100 will be awarded in 1956 by the Royal Society of Edinburgh for work on the therapeutical effect of X-rays on human diseases. Both published and unpublished work may be submitted. Applications and copies of relevant papers must be sent to the General Secretary, Royal Society of Edinburgh, 22 George Street, Edinburgh 2, not later than March 31.

Applications are invited for a Drummond senior fellowship and not more than two Drummond junior fellowships for research in nutrition, both tenable for two years. The senior fellowship will be worth £900 a year with research expenses not exceeding £50, and up to £90 a year for superannuation, and the junior fellowship will be worth £500 a year, with research expenses not exceeding £75 a year. Application forms, to be returned by January 27, and further information can be obtained from the Honorary Secretary, Drummond Trust, University College, Gower Street, London, W.C.1.

The authors of the article entitled "Laboratory Design", published in *Nature* of November 26, p. 999, write: "This investigation was assisted by a grant made by the Agricultural Research Council to the Nuffield Foundation. Acknowledgments also are due to Sir William Ogg, director of the Rothamsted Experimental Station at Harpenden, and to Prof. H. D. Kay, director of the National Institute for Research in Dairying, Shinfield, Reading, and their staffs for giving facilities for the survey described. and to the Trustees and Director of the Nuffield Foundation for permission to publish the work".

# ENGLISH STYLE IN SCIENTIFIC PAPERS

SINCE the publication in *Nature* of November 5 of Dr. J. R. Baker's article on the use of English in scientific papers and the accompanying editorial article, we have received a number of letters commenting on the situation. We print below a selection covering the main points raised.

---

DR. J. R. BAKER asks, "How can the standard of English in scientific journals be improved ?" It is true that I have sometimes been conscious of an uncharitable desire to be able to write book reviews in the style of Macaulay, a desire which I should presumably not have experienced if I had not read Macaulay ; but I do not believe that any substantial improvement will be brought about, at the level which matters most, by relying on the too comfortable doctrine that 'good reading makes good writing'. If standards are to be raised, those concerned with the education and training of scientists, from the early forms of the grammar schools onward, must believe that the writing of good English is important; and must make the weight of their belief felt by means of appropriate sanctions—by making pupils rewrite slovenly essays, by refusing to approve badly written Ph.D. theses, and so on.

But surely the short answer to Dr. Baker's question is "by the refusal of editors to print bad English". When I started to write scientific papers, most of them were edited by the late Dr. Clarence Smith, to whom I owe a great debt of gratitude for what I was at first inclined to regard as tyrannical restriction ; on many occasions he showed me how economy of words and clarity of expression went hand in hand, and even when I could not agree with his alterations, I benefited by being forced to think hard about my writing. I am sure that editors still help young authors in this way ; but I believe that the more ruthless use of the editorial pen could do much to raise the standard of English in our scientific journals.

On points of detail may I remark first that, although the principles involved in their correct use may be simple enough, in my experience the best advice to give about gerunds and present participles is to avoid them ; thus the phrase "on opening the body-cavity" used by Dr. Baker could easily be incorrect in a slightly different context, so that it is much safer, and on the whole more direct, to write "when the body-cavity is (was) opened". Secondly, much clumsy periphrasis is caused by our avoidance of the first person ; could we not agree that clarity is more to be prized than false modesty ?

University of Leeds.

---

IN his excellent article, Dr. J. R. Baker justly says that understanding is impeded by the misuse of words and by perverse or slovenly syntax. I would like to direct attention to a related problem : the growing inadequacy of the language itself as a means of expression. There are already too few words available to writers and the situation is growing worse.

Since the industrial revolution, the rate of appearance of new things, new activities, and new qualities has been faster than ever before in the world's history. At the same time, universal education, the spread of literacy, and a willing subjection to the tyranny of the dictionary have restricted the introduction of new words.

Sea-going folk are adequately supplied with words ; words which were originated by seamen were afterwards authorized by the dictionary-makers. But the language of aviation is sterile. We have a few cumbersome terms : bomber, fighter, airliner, seaplane, monoplane, biplane, and so forth, some of which have courageously been invented to meet an obvious need. But the rate of invention is not high enough. This is especially noticeable when something new appears. The Rolls-Royce jet-lifted vehicle is a good example of this. Clearly this is a member of the class of aerodynes ; but it is neither an aeroplane nor a helicopter. What are vehicles of this kind to be called ? Need we descend to the facetious and use such terms as 'flying bedstead' to describe a most advanced piece of engineering.

What are we to do about guided missiles ? Many different kinds are being developed now, and the only way of describing them seems to be with the aid of abbreviations, SSM, ASM (surface-to-surface missile ; air-to-surface missile) and so on. Many of them use rocket propulsion. But what is a rocket ? It used to be the complete vehicle, comprising propulsive means, stabilizing means, container and payload ; but as the vehicles grow bigger and we approach space-ships, the word is becoming limited to the motor itself.

Since there is, in fact, no shortage of letter combinations (nor of sound combinations) there seems no reason why new words should not be made concurrently with new things. It is in fact true that there have been considerable successes in this way ('radar' is a good example), but we need many more. The main requirements are common sense and courage. There will be many who will resist any attempt to introduce a word that is not already in the dictionary. Such people may be quite prepared to avail themselves of a modern product such as a cathode-ray tube, but they will not have the grace to allow it a word of its own.

---

DR. J. R. BAKER's description of some symptoms of a linguistic disease will have delighted all concerned with problems of information. May I point out two more of its deplorable effects : (*a*) the many Continental authors who now write directly for British or American publication may be led to take it as a model, neglecting the study of the very real virtues of American (not to mention English, which some of us in our old-fashioned way think equal to any task, even if it does not make up into such comfortably broad-bottomed volumes) ; and (*b*) now that printing is costed almost to the last 'en', one not only has to suffer this pompous verbosity, but also to pay extra for it.

P. J. EDMONDS

Cleaver-Hume Press, Ltd.,
Publishing Division,
31 Wright's Lane, London, W.8.

Dr. John R. Baker and the Editors of *Nature* have indicated some of the unhealthy symptoms in contemporary scientific writing and have made constructive suggestions regarding diagnosis and treatment. One fundamental factor which they have still overlooked is the almost universal evasion of the word "I", which evasion, in my opinion, is responsible for much of the circumlocution, artificiality and apparent 'genteelism' and 'grandiloquence' of scientists and bureaucrats alike.

There is one standard objection to the use of the personal pronoun: that it is immodest in a research worker because it imparts a personal flavour when science should be impersonal as well as unbiased. The psychologist McDougall[1] has trenchantly refuted this argument: "There is a common form of egotism which consists in ostentatiously avoiding the appearance of egotism. In conversation one avoids the words 'I' and 'me' as though they were among the most disgraceful in the language; one finds oneself most at ease with persons who do not offend one's susceptibilities with blatant egotism and who can appreciate one's freedom from that gross fault, a fault one cannot tolerate. In writing, and especially in early efforts, one refers not infrequently to 'the present writer' or 'the author of these pages', and uses other ponderous circumlocutions in the effort to avoid the solecism of appearing in the first person".

I doubt very much whether ignorance of basic grammar constitutes a major difficulty for the average scientist of research calibre, or whether he really needs more than the occasional second opinion of a friend or the occasional consultation of "Fowler". It is rather that the scientific author, like the official or the honorary official, somehow feels that everyday language is not quite important enough for his purpose. One junior worker among many who have commenced a paper on the lines: "Working out a collection of animals from Katmandu, three new species were found", listened politely as I asked if he realized that he had perpetrated, not only a grammatical monstrosity but an idea-picture which, taken literally, would need a Lewis Carroll or an Edward Lear to do it justice. Would he speak in that way? Would he describe his work in just those words in a letter to a friend? "Well, no," he answered, "but looking through other people's papers I thought that was how you were supposed to write."

I believe that the kernel of the whole problem lies in the individual's choice of reading. Laymen and scientists alike who have delighted in the lucid and majestic language of one of the greatest living masters of English prose, may well ponder Sir Winston Churchill's account[2] of the days when he took his own education in hand and set out to read Gibbon's "Decline and Fall of the Roman Empire" because "Someone had told me that my father . . . knew whole pages of it by heart, and that it had greatly affected his style of speech and writing". Let every young biologist, for example, take Aldous Huxley's essay[3] as guide and soak himself in the writing of T. H. Huxley. Let him read (in translation) the communications of old Antony van Leeuenhoek[4], as fresh now as when they were written more than two hundred years ago, as precise as the most puritanical of pure scientists could desire, as concise as the most frugal editor could demand and, incidentally, bristling with I's and none the worse for them.

There will be those who, once the elementary requirements of accuracy and brevity have been met, will belittle the importance of literary style in scientific writing and will apply the adjective 'literary' out of criticism, pity or simulated contempt. I think they will be profoundly wrong to do so. Until a few decades ago scientists and technicians combined with statesmen, public officials, lawyers, clergymen and popular novelists to form an influential community adequate to maintain the purity of our language. To-day the balance of power has changed for the worse. The age of Newspeak may be even closer than Orwell[5] prophesied.

It is stated in *Nature* of November 5 that "The time does not seem far away when high school pupils will have to learn a new table of symbols apart from those atomic". It would, however, appear that such a sad state already exists, the symbols and abbreviations being too numerous for a mere twenty-six letter alphabet.

Another difficulty is that the pupil has to know several glossaries of symbols, to be in line with different authorities.

# USE AND ABUSE OF PROTECTIVE EQUIPMENT

The fifth conference of the British Occupational Hygiene Society was held in London on November 4, the theme of the conference being "The Use and Abuse of Protective Equipment". It was divided into four sections dealing with the protection of the lungs, skin, eyes and feet. The proceedings will be published in the March issue of the ***British Journal of Industrial Safety***, and reprints will be obtainable from the honorary scientific secretary of the Society, D. Turner, Environmental Hygiene Research Unit, M.R.C. Laboratories, Holly Hill, London, N.W.3.

The morning session was opened by S. H. Wilkes (senior chemical inspector of factories), who warned against using the canister respirator inside tanks, stills or other closed spaces where there may be high concentrations of toxic gases or where shortage of air is possible. Papers on the protection of the lungs were presented by A. C. Peacock, of the Chemical Defence Experimental Establishment, Porton, and by J. Whittaker, of the Central Safety Department, Imperial Chemical Industries, Ltd. After stating that the only fully satisfactory method of protection of the lungs is by suppression of the risk at source, Mr. Peacock described the different respirators available for use when the ideal cannot be realized.

Characteristics necessary in types suitable for continuous wearing have necessitated a compromise in design between degree of protection and acceptability to the wearer. A review of the standard of protection demanded will sometimes result in a very much more wearable device.

Mr. Whittaker emphasized the importance of a good fit of face-pieces, which is easier to secure with full-sized face masks, going under the chin, than with the small kind covering only the mouth and nose. The larger the protective appliance, however, the greater is the aversion to wearing it and the risk of its being surreptitiously discarded. Discipline in the atomic energy field in this respect is better than in older industries because the workers are well aware of the danger and are accustomed to imperceptible risks.

The second section of the conference consisted of papers on the protection of the skin by Prof. J. R. Squire, of the Department of Experimental Pathology, University of Birmingham, and by Dr. A. Lloyd Potter, of the General Chemicals Division, Imperial Chemical Industries, Ltd. Prof. Squire described how the outer layer of the skin is chemically inert but swells in alkalis and, being a protein, can react with or absorb substances containing $-NH_2$ or $-SH$ groups. It can be destroyed by reducing agents and cracked if dried excessively. Loss of water is normally impeded by a surface film of fatty material which is replenished naturally after removal with solvents in about two hours. Mechanical abrasion, leading to wear of the horny surface faster than the germinal layer can replace it, is occasionally encountered in industry. Chemical irritants produce their effect rapidly when they act as sensitizers, in which case an intense reaction may follow a second exposure, even to very small quantities, after an interval of ten to fourteen days. Carcinogens require years to produce even precancerous effects, and the peak incidence of skin cancer is twenty to thirty years after exposure. Repeated exposure is necessary, and the action decreases when less of the carcinogen reaches the skin.

Dr. Lloyd Potter said that in order to affect the skin a substance must wet it, either by being itself liquid or by solution in perspiration or other liquid. Water, alcohol and weak acids do not greatly affect the skin; but alkalis and fat solvents penetrate to the sebaceous layer. Liability to dermatitis is not detectable at pre-employment medical examinations. Protection of a process by complete enclosure may be nullified if the final product is packed by hand. Protective clothing should not add to the risk of contracting dermatitis by causing sweating and chafing. Proper washing facilities should be provided for and used by workers, and, in this connexion, barrier creams are good because they encourage washing.

Speakers in the afternoon session were introduced by Sir Harold Roberts (chief inspector of mines), who stated that mining is the most dangerous of industries, being closely followed by shipping in respect of fatalities. The death-rate in coal mining is nine times as high as the death-rate in factories, major catastrophies being responsible for only a very small proportion of the casualties in mines; the major toll is taken by falls of ground and by transport operations. Owing to improved standards of lighting, the incidence of nystagmus has been greatly reduced.

Dr. D. R. Campbell, director of research, Birmingham and Midland Eye Hospital, in a paper on ocular injuries and hazards, said that eye injuries constitute 4·26 per cent of all industrial accidents and are mostly preventable, being due to flying particles. Goggles are liable to steam up; they restrict vision and are uncomfortable to wear. They are better received if the worker is given a number of kinds to choose from. Ocular injuries are often repairable, now that the complication of infection is largely absent, but even a small scar on the centre of the cornea can cause dazzle in artificial light. Eye protection, she said, should be compulsory when striking and chipping with metal tools. Burns from molten metals and chemicals, especially caustic soda, are dangerous, though immediate irrigation with water may save an eye.

The legal obligation to provide eye protection against certain hazards was then explained by G. V. Thom, safety officer, Plastics Division, Imperial Chemical Industries, Ltd. Protection built in to a machine is more desirable than protecting the operator, and he showed typical examples. Various devices for personal eye protection were described. In the particular case of welding, protection against infra-red rays is needed, and against ultra-violet as well in electric-arc welding.

H. Bradley, director of the British Boot and Shoe and Allied Trades Research Association, was the first speaker in the session on the protection of the feet, and outlined the steps which have led to the drafting of British Standards for safety footwear. These contain a steel toe-cap which has to resist an impact test. He was followed by H. E. Thomas, head of the Safety Department of the Ford Motor Company, who said that, in his experience, the standard safety boot did, in some cases, give protection but that many toe fractures while wearing them continue to arise. He thought these could be avoided by extending the toe-cap backwards. It is true that it would then be unable to pass the impact test, but it is evident that considerable deflexion of the toe-cap is possible without injury to the wearer's foot.

C. N. Davies

# THE FUNCTION OF LIBRARIES

At the annual conference of the Library Association, held in Southport during September 20–23, two speakers concerned themselves particularly with the university library. Sir Philip Morris, in his presidential address on September 20, drew on his experience in visits to universities overseas since the Second World War, when he found that there was no university which was not either replanning or developing its library, designing a new library and library service, or had just completed some new library undertaking. In Canada and the United States last year he saw, and discussed with those responsible for, five large new libraries completed within the past two or three years. All were different, and while there appeared to be no single answer to the problem of library design, the physical environment, arrangement and facilities of a library profoundly affected its service, and there appeared to be a growing need for much more co-operation and interdependence between libraries. Sir Philip believes that the efficiency of a university might be said to be a function of the adequacy and efficiency of its libraries, and, apart from this factor of co-operation, he emphasized the importance of books being available in suitable circumstances for the reader, and especially the importance of high standards of education and professional ability on the part of the library staff.

These points were elaborated more fully later at the conference by Dr. L. W. Sharp in a paper entitled "What do we look for in a University Library?" Dr. Sharp said little of library co-operation, believing it to be in a very healthy state so far as university libraries are concerned. He referred, however, to some of the difficulties occasioned by departmental libraries and made some suggestions for co-operation here in regard to book selection, exhibits and the like. Like Sir Philip Morris, he stressed the supreme importance of the quality of the library staff, referring to the importance of a university librarian having other academic interests and of encouraging his assistants to widen their interests, for example, through exchanges of staff with other libraries at home and abroad and by the provision of more research scholarships for special library projects. On the subject of library design, he emphasized, like Sir Philip, the importance of having regard to individual circumstances, as well as to the needs of the reader, and commended specially the provision of some rooms for special collections. He stressed particularly the principle that the university library is equally for masters and scholars, and that students should have as free access as any other readers. He does not think that the division into a scholars' library and a masters' library, from which scholars are excluded, is sound; the aim should be to let the student feel that he is a member of a scholarly community and that he is welcome and his place is honourable.

Among the other papers presented to the conference, three were of particular interest to the scientist. They dealt with the general theme, "The Library in the Community", that of Mr. W. S. Haugh (city librarian, Bristol) reviewing the public library service in general. Mr. Haugh said that only fifteen English municipal authorities serving populations in excess of a hundred thousand exceeded 1*s*. 6*d*. per head of population in their expenditure on books during 1952–53, whereas nine spent less than 10*d*. per head as against the 2*s*. suggested as standard in the centenary assessment brochure. For the counties later figures are available, and seven English county authorities are estimated to exceed 2*s*. per head in 1955–56 and seven others to be spending less than 1*s*. 3*d*. Of more specific interest to the scientific worker and technologist, however, were Mr. Haugh's observations on the importance of adequate expenditure on books in the schools and its bearing on educational efficiency, and what is being done by county libraries and other public library services to improve the facilities for educational reading for children as well as for students of technology and of other subjects. He referred particularly to some recent developments in the provision of technical information services by the public libraries, such as the scheme at Liverpool that provides for an immediate temporary technical library and a permanent technical library at a cost of £270,000; the establishment of technical library facilities at the Speke Branch Library serving the trading estate there, as well as branch technical libraries elsewhere; the extension of the Leeds commercial and technical library; the establishment of a separate technical department at Rugby; and the formation at Luton, where the central library maintains a large file of information on the requirements of the export trade, of the Luton and District Technical Information Service. He also mentioned the installation earlier this year in the Manchester Central Library of a teleprinter apparatus giving a direct link to more than a hundred users in the Manchester area, two thousand in the United Kingdom and twenty-five thousand in twenty-one centres abroad, and to the formation of co-operative industrial and commercial reference and information services among public libraries and business firms both in the West London and the North London areas.

Of the other two papers, Mr. H. Thompson (technical librarian, Lancashire County Library), dealing with technical library services in the county, described more particularly the nature of this service, emphasizing its bearing on technical education, and the importance both of mobility and of taking full account of the various requirements of the groups served. Mr. D. J. Foskett (librarian and information officer of the Metal Box Co., Ltd.), dealing with special libraries, also referred to co-operation in the technical field, and his paper was particularly valuable for emphasizing the necessity in all such schemes of remembering that the special library owes its first responsibility to the group by which it is maintained. If this is ignored, the special library can scarcely make its contribution either in co-operation or in the development of new techniques and improved services.

# ROTHAMSTED EXPERIMENTAL STATION

## REPORT FOR 1954

WITH the advent of any new agricultural problem that is amenable to scientific treatment, it has become almost a matter of course for the interested parties to ask: "What is Rothamsted doing about it?" Clearly it is impossible for any research station to follow up too many of the problems of the moment without dangerous dispersal of effort and neglect of fundamental aspects. It is therefore heartening to see that the annual report of the Rothamsted Experimental Station (Pp. 242. 7*s*. 6*d*., from Rothamsted Experimental Station, Harpenden) again reflects a most satisfactory balance between pure and applied research and in the choice of the problems being studied. It is also clear from the very large number of visitors from all parts of the world that the Station continues to play a vital part in the exchange of information.

In the Physics Department there have been further advances in the techniques for measuring micro-climates, and these methods are being used to study the conditions affecting the spread of virus diseases and of blight in potatoes. A new sodium-saturation test has been used to assess the increase in crumb cohesion caused by certain high polymers. It is interesting to note that some of these are more effective on acid than on calcareous soils. Work continues on the crystal structure of kaolinite.

Notable among a wide range of studies in the Chemistry Department are experiments on the placing of fertilizers. It has been demonstrated that some crops, including potatoes, benefit from the placing of nitrogen and potassium as well as phosphorus. Important progress has been made in the estimation of ammoniacal and nitrate nitrogen in soils, and fundamental studies are being made of mineral phosphates and of organic nitrogen and phosphorus compounds in soils.

The Pedology Department is closely linked with the Soil Survey and, in collaboration with the latter, a study has been made of the mineralogy of sand and clay fractions from a wide range of soils from Great Britain and the Colonial Territories. This work is providing important data on soil formation and classification. Progress is being made with the survey of trace-element distribution in British soils, and work continues on the effects of leaf leachates in soil-forming processes.

Investigations on the possibility of controlling disease fungi by antagonistic micro-organisms are in progress in the Soil Microbiology Department. It has now been shown that the action of Actinomycetes in suppressing the root fungus *Helminthosporum* is antibiotic and not merely competitive. Work continues on the strains of clover nodule bacteria which fail to produce effective nodules, and attempts are being made to select genetically stable strains for seed inoculation.

Studies in the Botany Department include the mutual interaction of iron and other micro-nutrients, the uptake of nutrients by plants through the leaves and by excised roots, and the physiological effects of virus infections. Work on kale has shown that there is an optimum leaf area, per unit area of land, for dry-matter production. If this is exceeded, efficiency falls off due to the mutual interference of leaves. Studies on weeds continue, with special attention being paid to wild oats.

The Biochemistry Department is mainly concerned with the study of representative enzyme systems, special attention being paid to the enzymes of bracken in the hope that measures of control may ultimately result. Various oxidation systems are also being studied, and progress has been made in designing a press for the large-scale extraction of protein from fresh leaves.

Work in the Plant Pathology Department seems to indicate that, in newly inoculated leaves, virus particles are continually synthesized and broken down and that the ratio of breakdown to synthesis increases with temperature. Among much other interesting work on virus diseases, it has been shown that the incidence of yellows in sugar beet is much reduced by systemic insecticides. Mycological studies have been carried out in relation to a number of crops, and the value of soaking sugar-beet seed in ethyl mercury phosphate has again been emphasized.

In the Nematology Department intensive study is being made of eelworms, their relationships to host plants and the conditions under which populations build up. Surveys at Rothamsted show that increases of eelworm cysts on plots under continuous mangolds and sugar beet have been very slight during the past eight years, but that the highest densities are associated with manurial treatments giving the highest yields.

Research has continued in the Insecticides Department on the mode of action of organo-phosphorus insecticides and, in particular, on their interaction with the esterase systems of various insects. Useful work is reported on practical methods for controlling black aphis on beans and the wheat bulb fly, and progress has been made in rearing the latter in the laboratory.

The biology of the wheat bulb fly is also being studied in the Entomology Department. Work continues on the dispersal of aphids and on the biology of their natural enemies. Interesting studies of gall midges of various plants are reported, in particular the Hessian fly and the midges of white clover, the latter being especially important in relation to the production of clover seed.

The Bee Department once again presents a fascinating research report on foraging habits and social organization. It has been shown that the foraging of bees may be induced by the release in the hive of a scent which they have learnt to associate with food, and this may have great importance in problems of directing bees to particular crops. The sharing of sugary substances collected by one bee with the other members of a colony (using syrup containing carbon-14), the nature and functions of 'queen substance' and trials of acaricides are among other studies reported.

An electronic computer has now been installed in the Statistics Department, and an intensive study is being made of its potentialities. The survey of hill and livestock-rearing farms is complete and will indicate what scope exists for further expenditure on upland farms. Surveys of fertilizer practice and rabbit damage continue.

The report closes with two useful review articles on "Clay Minerals" and on "The Uptake of Nutrients from Leaf Sprays by Agricultural Crops".

# EAST MALLING RESEARCH STATION

## REPORT FOR 1954

THE forty-second annual report, for 1954, of the East Malling Research Station, near Maidstone, Kent (170 pp., 12*s*. 6*d*. post paid from the Station), includes two general papers of particular interest. The first is the text of the seventh Amos Memorial Lecture, by Prof. T. A. Bennet-Clark, who reviews various concepts of the mechanism by which water ascends large trees, showing that this is not yet fully understood, and makes a plea for more research on the matter. The second is by S. C. Pearce and D. W. P. Greenham, and is a history of the Station's land in the parish of East Malling. It has been possible to trace certain land uses as far back as A.D. 1411, and such historical investigations might achieve useful correlation with modern soil survey.

Malling types of apple rootstocks are now famous, and H. M. Tydeman gives a most useful summary of the twenty-four types, and also crab *C*. His text is very short, but five tables and thirty-five excellent half-tone illustrations give very detailed information about winter and summer characters. D. W. Way, E. S. J. Hatcher and R. J. Garner have investigated the propagation of rootstocks by means of root cuttings. Position on the original root system, length, moisture relations, depth of planting, and various methods of coating the cut ends, have all been assessed, and detailed results are presented. The two last-mentioned workers have also experimented with propagation of Malling crab *C*, by sphæroblast cuttings. Sphæroblasts are rounded swellings on woody stems which are able to produce shoot buds—sufficient to yield some twenty-five hardwood cuttings per maiden tree. The peach variety Hale's Early is compatible with a Brompton rootstock, though not

## The Biochemistry of Vitamin $B_{12}$

EDITED BY R. T. WILLIAMS

Vitamin $B_{12}$ was first isolated in 1948. It is now generally accepted as the anti-pernicious anaemia factor long known to be present in liver. Various aspects of Vitamin $B_{12}$ are discussed in this 13th Symposium of the Biochemical Society. *20s. net*

## Hydrodynamic Stability

C. C. LIN

This is the first survey of Hydrodynamic stability. It treats both the physical and mathematical aspects, and will be of particular interest to aeronautical engineers. A CAMBRIDGE MONOGRAPH ON MECHANICS AND APPLIED MATHEMATICS. *22s. 6d. net*

W. E. CLASON of Philips Eindhoven edits this meticulous, comprehensive and ingenious aid to research and technical writing. 750 pp. £6

## *Communication News*

This journal of Philips Telecommunication Industries covers both electrical and mechanical aspects, reporting current problems and studies at full length with fine illustrations. Volumes appear over about a year, in 2–4 issues of 32–64 pages. Volume 16 has now begun. Annual subscription 14s. *Free specimen back number on request.*

*From Philips Technical Library*

## *Light Measurement and Calculations*

H. E. A. KEITZ. 420 pp. 225 illus. 52s. 6d.

"He has been highly successful, achieving a maximum of clarity without any sacrifice of accuracy."—J.W.T.W. in *Electrical Review.*

## *Illuminating Engineering Course*

H. ZIJL 250 pp. 128 illus. 23s. 6d.

A short study of the theory and its application, using only simple mathematics and with 170 questions and model answers.

## *Data for X-Ray Analysis*

W. PARRISH *et al.* $8\frac{1}{2} \times 11\frac{1}{4}$. Each book 15s. These data-books supplement the charts and tables of the Int. Union of Crystallography. Vol. I: **Charts for Solution of Bragg's Equation** (d=$\theta$ and $2\theta$). Vol. II: **Tables for Computing Lattice Constant of Cubic Crystals.**

*Fully descriptive Catalogue on request*

A comprehensive survey of the world literature

**British Abstracts of Medical Sciences**

*EDITOR:* ***C. C. N. VASS**, M.Sc., Ph.D., M.B., Ch.B.*

British Abstracts of Medical Sciences is now published on behalf of the British Council of Biological & Medical Abstracts, Ltd., by Pergamon Press, Ltd., who have undertaken the publication of the journal on a **non-profit-making basis** to assist with its development. The journal at present abstracts the world literature in 26 subjects in Medical and allied Sciences, but it is proposed gradually to increase the coverage to include Gerontology, Helminthology, Food Technology, Veterinary Science, Systematic Zoology and Economic Entomology. Plant sciences are to be covered for the first time and will include Ecology, Forestry, Pharmaceutical Botany, Pharmacognosy, Phytopathology, Plant Anatomy, Plant Physiology and Systematic Botany. The wider range of subjects covered will necessitate an expansion of production to more than one volume per year. In 1956 two volumes will be produced, each of about 600 pages. The price per volume is to remain the same at £10, or £10 10s. printed on one side of the page.

# MACMILLAN BOOKS

## Theoretical Hydrodynamics

L. M. MILNE-THOMSON

This book gives a thorough introductory exposition of the mathematical theory of fluid motion. For the third edition Prof. Milne-Thomson has introduced some new methods of presentation, and made three important additions dealing respectively with : the physical interpretation of virtual mass ; the method of reflection across free streamlines, which greatly simplifies the discussion of Helmholtz motions ; the treatment of potential flow with a free surface. *Illustrated.* 60*s.*

## Arithmetic Operations in Digital Computers

R. K. RICHARDS, Ph.D.

This text has been written to point out the shortcomings of pencil-and-paper rules and procedures when applied to computing machinery and to explain the more important of the schemes which have been worked out for executing arithmetic operations in that class of machinery generally known as 'digital computers'. 52*s.* 6*d.*

## General Microbiology

WILLIAM G. WALTER and RICHARD H. McBEE

This text is presented so as to encourage a beginning student to relate his daily living to the activities of the microbial world and at the same time to acquire a scientific approach which will permit him to pursue more advanced courses in microbiology. *Illustrated.* 35*s.*

## Descriptive College Physics

HARVEY E. WHITE

*Professor of Physics, University of California*

This book is a revised and compressed version of the same author's *Classical and Modern Physics*, which was intended originally as a short course for University students requiring some knowledge of physics, though not specialising in the subject. The general plan of the work remains the same, and the reduction in subject matter has been effected because the earlier book contained more material than necessary for such a course. *Illustrated.* 42*s.*

**Blood Group Substances**

**Their Chemistry and Immunochemistry**

By ELVIN A. KABAT
*Columbia University, New York*

**February 1956, 330 pp., illus., about 64s.**

IN THE AUTHOR'S own words, "the present volume is an attempt to bring together and to synthesize the existing information on the blood group substances as seen from the viewpoint of quantitative immunochemistry." The preparation of this book was stimulated by the extraordinarily increased interest in and knowledge of blood groups witnessed during recent years. Immunochemistry, immunology, carbohydrate and protein chemistry, physical chemistry and thermodynamics, genetics, as well as clinical medicine all contribute to this survey of blood group substances, and, in turn, investigations in these fields are benefiting from the newer knowledge of blood groups.

*CONTENTS:*

Introduction—The Human Blood Group Factors
Methods and Reagents Used in Testing for Blood Group Antibodies and Antigens
Sources of Blood Group Substances
Purification of Blood Group Substances
Chemical Composition and Properties of the Blood Group A, B, O (H) and Le$^a$ Preparations
Chemical and Immunochemical Characterization of the Blood Group Substances—Evidence of Purity
Immunochemical Similarities and Differences Among Blood Group Substances from Various Species
Some Features of the Structure of the Blood Group A, B, O (H) and Le$^a$ Substances
Antibodies to Blood Group Substances and Their Biological Effects
Biological Effects and Uses of Blood Group Substances—Materials of Similar Chemical Composition
Author Index—Subject Index.

## AN INTRODUCTION TO LINEAR ALGEBRA

by L. MIRSKY

This book provides a systematic introductory account of linear algebra, designed to meet the needs of students reading for an honours degree in mathematics. No previous knowledge of the subject is assumed.

The text contains illustrative exercises, and each chapter ends with a set of graded problems. 35*s. net*

NEW BOOKS

## Techniques in Blood Grouping

IVOR DUNSFORD
and C. CHRISTOPHER BOWLEY,
M.B., B.S., M.R.C.O.G.

Written by the Senior Scientific Officer and the Director of the Regional Blood Transfusion Centre, Sheffield, this is a practical manual which will be invaluable to all concerned with blood groups. It consists of three sections, 1. Description of basic principles of red cell antigen and antibody behaviour on which techniques are based, and suggestions on organisation and method in the laboratory, 2. Step by step details of systematic techniques, 3. Glossary of terms and symbols used in blood group serology.

It is the only book so far published which describes systematically the detailed laboratory techniques employed in blood grouping.

264 pages. Illustrated. 21*s.* net.

## The Numbers of Man and Animals

edited by J. B. CRAGG and
N. W. PIRIE, F.R.S.

This is the record of a symposium held by the Institute of Biology with the aim of bringing together specialists in many different subjects connected with the numbers of man and animals in order to discover how much common ground existed. The statistical, mathematical, medical, biological and anthropological aspects of the subject are all fully represented. Each paper is followed by a table of references to literature cited and a summary of the discussion by other members of the symposium. Thus a valuable balance of opinion is achieved.

*Published for the Institute of Biology*

160 pages. Line diagrams. 15*s.* net

## Principles and Applications of Physics

OTTO BLUH, D.Sc., F.Inst.P.,
and JOSEPH D. ELDER, A.B., A.M.

The need for a comprehensive survey of physical science which can be of service to the student of physics as well as to the specialist in other fields is met by this book. Original in its approach, this thought-provoking university text is distinguished by its advanced methods of presentation and its emphasis on the border-fields of physics and the interrelations of physics with the humanities. A notable feature of the book is the large number of illustrations, of which there are over 700 in line and half-tone.

866 pages. Illustrated. 45*s.* net.

ARTIA

COLLECTION

OF CZECHOSLOVAK CHEMICAL
COMMUNICATIONS

(Founded by E. Votoček and J. Heyrovský)

This publication includes selected papers in the fields of chemistry and biochemistry translated from the Czech journal "Chemické Listy" into English, German and Russian. In addition to these full-length papers the journal also carries detailed summaries from certain other papers published only in Czech. Six issues totalling about 1600 pages appear annually. A complete bibliography of polarographic papers is published in the form of a Supplement.

Annual Subscription $8.50 or equivalent in local currency. Orders may be placed with ARTIA, 30 Ve Smečkách, Prague (Czechoslovakia), or any booksellers.

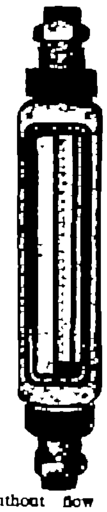
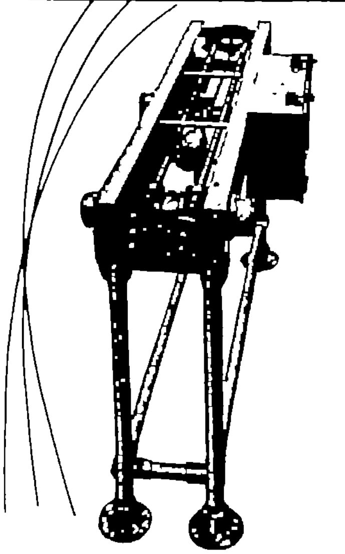
ROTAMETER
introduce several
NEW INSTRUMENTS





FLUID DENSITY

The RM DENSITY METER is based on the principle of continuously weighing a loop of pipe through which the fluid is flowing. A pneumatic force balance is used, the instrument output being 3-15 p.s.i. for density change of 0.2 grms/cc. Since the fluid is not subjected to any velocity change, *SLURRIES* can be handled without difficulty

*Send for leaflet 2040N.*

LIQUID LEVEL

THE "EKSTROM" SAFETY LEVEL INDICATOR is now being manufactured under licence. By use of a magnetic-coupled indicator all danger of gauge glass breakage is obviated

*Send for leaflet 2045N.*

RATE OF FLOW

METRIC SERIES ROTAMETERS with interchangeable glass tubes, full calibration data for liquids, and new mountings with minimum number of parts, all fully standardized

*Send for leaflet 2018N*

Leaflets are also being prepared on the following new products and we should be glad to place you on our mailing list:

(1) FLOW ALARMS, with and without flow indication

(2) ELECTRICAL TRANSMITTING ROTAMETERS, with details of a new High Speed Indicator. (0.8 secs for 15 in. pointer deflection.)

(3) INTEGRATOR, as additional fitment for series 500 indicating ROTAMETERS.

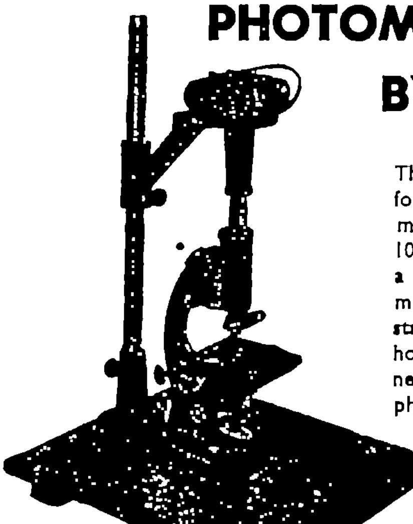

PHOTOMICROGRAPHY BY WRAYFLEX

The Wrayflex offers many advantages for photomicrography: economy in material, true reflex focusing with 100% of the light reaching the film, a simple adapter accepting standard microscope eyepieces and a rigid stand to support the camera which, however, can be instantly disconnected when required for normal photography.

The Wrayflex is particularly suited to macrography and copying work with its interchangeable lens range and extension rings. Write for illustrated brochure.

Rotifer Brachionus plicatilis. Magnification 45 × (original negative). Enlargement 1·5 Micrograph taken with the Baker Interference Microscope with ⅛ in. Shearing type objective × 5 eyepiece. Arthur L. E. Barron, F.R.M.S.

**SPECTROCHEMICAL ABSTRACTS**
**Volume IV, 1946-1951**

By E. H. S. van Someren, B.Sc., F.Inst.P., and F. Lachman, Dipl.Ing.

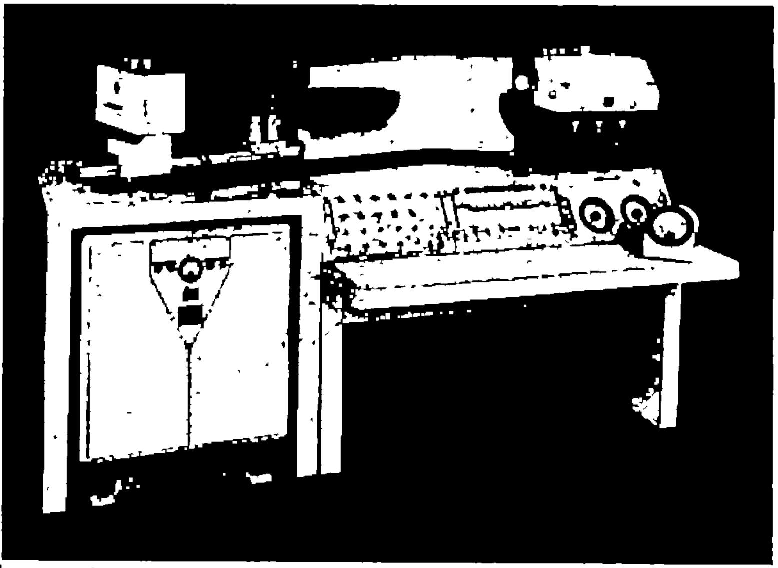
Published this month by Hilger & Watts Ltd.

A continuation of the first three volumes of this very useful guide to the literature of emission spectroscopy and flame spectroscopy. The abstracts, though brief, are systematically arranged to present the essential facts.

Royal Octavo, 180 pages, 827 abstracts, price 30s. net.

Some copies of Vol. I, 1933–1937, Vol. II, 1938–1939, and Vol. III, 1940–1945, are still available at 12s. 6d., 10s. 6d., and 12s. 6d. each, respectively.

A complete set of Spectrochemical Abstracts, Vols. I–IV, comprising 1689 abstracts, is available at 60s. net.



# Direct-reading analysis

Up to ten elements can be quickly and accurately analysed with the Direct Reading Attachment to the Hilger Medium Quartz Spectrograph.

The plateholder is replaced by a unit accommodating eleven slits and photomultipliers and the slits can be adjusted accurately on any desired set of spectral lines. The time taken for measurement is about 5 seconds per channel. Sensitivity is high and reproducibility is often better than that obtained with photographic methods.

This unit is now available in the convenient form shown in the illustration.

*Member of SIMA and SCIEX*

with Myrobalan *B*. Barbara Mosse shows that on a tree successfully established on a Brompton rootstock, incompatibility was induced by ring-grafting the Brompton stem with Myrobalan *B* bark, and the histology of the union is described. Papers on varietal performance and fruit management include two papers by A. P. Preston, on the results of variety trials of black currants over seven years, and an assessment over nine years of two systems of pruning the crop. Dorothy J. Wilson has measured the loss in yield due to the genetic conditions of Auchincruive Climax known as transient yellows and 'streak'. M. M. McNeill finds that apples grown in pots under glass require applications of dried blood to supplement the normal John Innes potting compost. D. W. Way and G. H. Freeman have bravely undertaken a very careful tasting trial of strawberries and raspberries, with results which are, nevertheless, somewhat of a surprise—at least to the present writer. Temperatures during night frosts were higher over compacted ground than over loose soil, according to C. H. W. Slater and J. P. Ruxton.

It is important that materials for the control of pests should not themselves cause damage, but H. W. B. Barlow, G. H. L. Dicker and J. B. Briggs found that parathion sprays against apple sawfly caused marked fruit drop. Yet parathion gave more significant increases in yield than gamma-benzene hexachloride and nicotine. Such increases were not due to control of the sawfly, and the mechanism by which they were obtained requires further investigation. H. W. B. Barlow, C. R. Hancock and H. J. Lacey have isolated certain heat-stable growth-inhibiting substances from woody shoots of crab *C* and Myrobalan *B* rootstocks. Changes in mineral nutrients in the leaves of the 'biennial bearer' apple Miller's Seedling were investigated by A. C. Mason, who has shown that larger concentrations of nitrogen, phosphorus, magnesium, calcium and manganese occur in the fruiting years than in the non-fruiting ones. A laboratory study by E. L. Frick of thirty materials for their relative ability to inhibit spore germination of *Botrytis cinerea* brought out some interesting divergencies between laboratory and field performance. Two of the substances—tecnazene and pentachlornitrobenzene—are already in use against the fungus, but did not inhibit spore germination. Thiram and the ferric, zinc and manganese dithiocarbamates, moreover, inhibited spore germination at two different concentration ranges.

Leaf roll, a new virus disease of the sweet cherry, is described by A. F. Posnette and R. Cropley. An attempt to clarify the relations between nettlehead and split leaf blotch viruses of hops has been made by J. T. Legg. Evidence for the view that the latter is a component of a complex causing the former is as yet inconclusive; but in this particular field trial, the relevant clones of College Cluster and Malling Midseason had the lowest amount of nettlehead of any variety tested. A. M. Massee contributes fifteen short notes on interesting insect records in 1954, perhaps the most important of which is an attack by cockchafers in two localities. He also reviews problems arising from the use of insecticides, and makes a plea for entomologists to study their effects upon the whole orchard fauna. Joan R. Groves reports that mercury-vapour light traps were found more efficient than bait traps for catching codling moths, while D. A. Chant and R. C. Muir find that the brushing machine method is superior to the imprint method for estimating numbers of fruit-tree red-spider mites. In the realm of statistics, G. H. Freeman and Margaret J. Hall point out that variations in number of red-spider mites from leaf to leaf, between trees, and also between plots, should all be considered when estimating the significance of control treatments.

There are, in the report, also accounts of all the activities of research sections and a description of the organization of the experimental farm. There are weather records and the texts of three bulletins for fruit-growers: on the search for better fungicides, by M. H. Moore; an illustrated description of capsid bugs, by Elsie Collyer; and on some impressions of apple orchard practices in Canada, by G. H. L. Dicker and A. H. M. Kirby. The volume is produced to the usual high standards of printing and illustration, and—most welcome—there is an index.

JOHN GRAINGER

# PATHOLOGY OF BIRDS IN ZOOLOGICAL GARDENS

A STUDY of the pathology of birds in the Zoological Gardens of Antwerp has been made by Prof. L. M. G. Geurden, of the University of Ghent (Bulletins de la Société Royale de Zoologie, d'Anvers, No. 4).

Bird diseases in zoological gardens are numerous and mortality is very high. The primary cause may be either in the country of origin or in the transportation, or in the zoological garden itself. In captivity, malnutrition, deficient food or lack of movement influence a large number of birds, although their susceptibility varies within wide limits from one individual to another.

In the period under review, Prof. Geurden dissected thirty-five dead birds; a laboratory analysis was often required for a definitive diagnosis. The most common causes of death were pneumonia (5), visceral gout (13) and hæmorrhagic enteritis (22). Pneumonia, quickly followed by death, is common in birds originating from tropical countries when exposed to low temperature. Isosporosis involving a primary disease is likewise very frequent. Captive birds often suffer from visceral gout; the great change in the way of living and in the nature of the food is doubtless the starting-point of this disease, although the susceptibility of different individuals varies considerably. Diseases such as cæcal coccidiosis and black head will affect all members of the gallinaceous group in the same way.

The majority of birds had died from hæmorrhagic enteritis. In the absence of intestinal parasites, the bacteriological test for detecting *Salmonellae* often shows a negative result. *Salmonellae* were cultivated seven times from the intestinal contents.

Birds are commonly considered as the biggest reservoir of *Salmonellae*; powdered eggs used during the War have shown this on a very large scale. In some cases latent infections occur, in others acute diseases develop. Although several internal organs may be the seat of these infections, they are more often found in the intestines and in the genital organs. Owing to the large number of *Salmonella*-types, the epidemiology of *Salmonella*-infections is quite confused, and, in his work, Prof. Geurden clarifies a number of points which have previously caused difficulties with various species and types.

# COMBINED AMINO-ACID CONTENT OF TUMOUR AND HOMOLOGOUS NORMAL TISSUE

By Dr. G. C. EASTY and Dr. E. J. AMBROSE

Chester Beatty Research Institute, Royal Cancer Hospital, London, S.W.3

IN the course of an investigation into the chemical and structural difference between tumour and homologous normal tissue, the combined amino-acid content of the normal kidneys of the male golden hamster was compared with that of tumours produced in them by treatment with stilbœstrol. This material is particularly convenient for such a study, since the tumours are very compact, consisting almost entirely of tumour cells, and are easily separated from surrounding non-tumour tissue. All tissue samples analysed were subjected to histological examination. Fourteen amino-acids were analysed by paper chromatography, using mainly the method of Roland and Gross[1], and to a lesser extent McFarren and Mills[2].

Initially, all hydrolyses were carried out in tubes sealed in air with 10 *N* hydrochloric acid, and a tumour hydrolysate was first compared with that of a whole normal kidney. The proportion of methionine in the tumour was 30–40 per cent lower than in the normal kidney, the other thirteen amino-acids being present in both tissues in almost identical proportions. The tumours arise from the cortex of the kidney, and it was thought possible that the cortex of the normal kidney might contain less fixed methionine than the inner medulla. This could account for the lower proportion of methionine in the tumour arising from the cortex. To test this a second tumour was compared with the normal cortex, normal medulla, and cortex adjacent to the tumour but free of any visible tumours. From the results in Table 1 it can be seen that, relatively, the cortex of the normal kidney contained if anything slightly more methionine than the medulla. Hence the decrease in methionine content of the tumour was not due to its being derived from the cortex. Furthermore, the methionine content of the tumour-free cortex of the tumour-bearing kidney was the same as that of the cortex of the normal kidney. A hamster kidney cortex, which had not formed tumours on treatment with stilbœstrol under the conditions which gave rise to tumours in other hamsters, contained the same proportion of methionine as the normal untreated kidney. Thus it appeared that a lower content of combined methionine is characteristic of this tumour. Significantly lower quantities of tyrosine were found in the tumour compared with most of, but not all, the other tissues; but the deficiency was not so great. Ten tumours have been analysed so far, most of them at least twice, and in no case has the methionine content failed to be less than that of the whole normal kidney, cortex and medulla.

Tissues to be compared were so far as possible obtained at the same time, fixed as soon as possible by immersion in 3 volumes of ethyl alcohol and 1 volume of glacial acetic acid, or in absolute ethyl alcohol alone for one hour, washed with absolute ethyl alcohol and stored in that solvent. The chopped samples were extracted for equal lengths of time with chloroform to remove lipids, dialysed in the same vessel to remove low-molecular weight compounds, and equal weights sealed in tubes containing hydrochloric acid, either with enclosed air or evacuated; they were hydrolysed at 110° in an oven, side by side, for 18 hr. Two analyses of one hydrolysate on the same sheet of paper almost always agreed to within ±5 per cent for each amino-acid, and hydrolysates to be compared were always run on the same sheets.

On comparison with previous analyses for kidney and liver, it was found that we were obtaining lower values for the quantities of methionine and tyrosine present. As most previous workers had hydrolysed their tissues in 6 *N* hydrochloric acid and not 10 *N*, it was thought that lower values might be due to more extensive degradation of these amino-acids by the more concentrated acid. On hydrolysis of the same sample of normal kidney with 6 *N* and 10 *N* hydrochloric acid in sealed tubes with air it was found, however, that as much loss of tyrosine and

* All hydrolysed in sealed tubes with air. † Hydrolysed *in vacuo*

methionine occurred in 6 *N* acid as in 10 *N* acid. But it was found that when the same sample was hydrolysed in 6 *N* or 10 *N* acid *in vacuo*, the values for methionine and tyrosine rose, and they compared favourably with those obtained by previous workers. It appears that the presence of air rather than the concentration of acid is causing the loss of methionine and tyrosine.

Of greater importance was the observation that, when hydrolysed *in vacuo*, the normal and tumour tissues contained on analysis equal quantities of methionine and tyrosine. There are several possible explanations for the observed and consistent difference in the degree of degradation of individual amino-acids present in normal and tumour tissues hydrolysed side by side under identical conditions.

(1) The tumour tissue could contain more of certain contaminating substances such as nucleic acids and polysaccharides which might catalyse degradation. The hydrolysis of normal kidney and tumour in the presence of added 10 per cent deoxyribonucleic acid and 10 per cent polysaccharide in 6 *N* hydrochloric acid *in vacuo* was therefore carried out. It resulted in no significant loss of any amino-acid compared with the hydrolysis of these tissues alone under the same conditions. Possible losses of methionine during chromatography caused by the presence of more contaminating substances in the tumour hydrolysate than in the normal hydrolysate were tested for by adding equal known quantities of methionine to both hydrolysates. The recovery of added methionine in both cases was the same, about 90 per cent, that is, a 10 per cent loss, similar in magnitude to that found by Moore and Stein[3] using polystyrene columns.

(2) The tumour tissue might contain more of certain catalysts, such as trace metals, which are known to catalyse the oxidation of methionine. This was investigated by adding equal quantities of methionine to equal weights of tumour and normal tissue before hydrolysis *in air*. If there is no greater loss of the methionine added to the tumour than of that added to the normal tissue, then the difference in degradation observed with normal and tumour tissue alone cannot be caused by catalysts. Thus, if no more catalysis occurs in the tumour hydrolysate than in the normal hydrolysate, then:

$$\underset{\text{(Normal tissue + added methionine)}}{\text{Methionine}} - \underset{\text{(Normal tissue)}}{\text{Methionine}}$$

$$= \underset{\text{(Tumour tissue + added methionine)}}{\text{Methionine}} - \underset{\text{(Tumour tissue)}}{\text{Methionine}}$$

The figures found, in milimoles, were:

$$\underset{(N + A)}{\text{Me}} - \underset{(N)}{\text{Me}} \quad \text{and} \quad \underset{(Tu + A)}{\text{Me}} - \underset{(Tu)}{\text{Me}}$$

$$1{\cdot}4 - 0{\cdot}65 = 0{\cdot}75, \qquad 1{\cdot}15 - 0{\cdot}33 = 0{\cdot}82$$

Therefore, the added methionine was degraded to an almost equal extent with both tissues—if anything to a slightly smaller extent in the tumour hydrolysate.

This leaves explanation (3), namely, that there are significant differences in the structure and/or amino-acid sequence of the proteins of the normal and tumour tissues. It is known that free methionine is partially oxidized during acid hydrolysis in the presence of air[4], and it seems probable that the greater loss of methionine and tyrosine in the tumour hydrolysate than in the normal kidney hydrolysate is due to the fact that the tumour proteins are hydrolysed more rapidly, the amino-acids being released more quickly, thus allowing more time for oxidation to occur.

Recent work by Smith and Stockell[5] on the composition of carboxypeptidase has shown that the apparent loss of certain amino-acids on hydrolysis depends on factors which appear to vary with different proteins. In addition, it is now recognized that peptide bonds involving, for example, isoleucine and valine are difficult to hydrolyse. Hirs, Moore and Stein[6], in their work on the composition of ribonuclease, found that no decomposition of acidic amino-acids was observed when synthetic mixtures were 'hydrolysed', whereas some loss was observed when ribonuclease was hydrolysed under the same conditions. Similarly, Smith *et al.*[7], found that no destruction of glutamic acid occurred on hydrolysis of carboxypeptidase, but that destruction occurred on hydrolysis of crystalline papain under identical conditions. Differences in the rates of release and degradation of the same amino-acids from tumour and homologous normal tissue might account for different results obtained by different workers on the same materials. Schweigert[8] found that the whole homogenates of tumours obtained from the livers of rats treated with 4-dimethylaminoazobenzene contained 33 per cent less methionine and 28 per cent more cystine than the normal livers. Sauberlich and Baumann[9] carried out similar analyses on the same tumours but found no deficiency of methionine or increase of cystine. The conditions of hydrolysis were not, however, identical in both cases, different concentrations of acid being used for different periods of time.

The suggested greater ease of hydrolysis of tumour proteins under these conditions fits in with the idea put forward by Ambrose[10] that the tumour proteins are characterized by a more random structure which should facilitate attack by hydrolytic and other agents. There is evidence[11] that proteolytic enzymes first act by denaturing the protein, reducing the degree of order. Thus, increased randomness of tumour proteins might facilitate hydrolysis even in acid solution without the intervention of enzymes. It is of interest to recall that Rondoni[12] has suggested that carcinogenesis is accompanied by denaturation of the cell proteins. The observations of Kögl and Erxleben *et al.*[13] concerning the presence of more D-glutamic acid in tumours than in normal tissues, about which there has been much controversy, might be explicable in terms of differences of protein structure leading finally to the isolation of a more highly racemized glutamic acid from the tumour than from the normal tissues.

From our work we conclude that, within the limits of error of the analytical method used, there appears to be no significant difference in the overall amino-acid composition of normal hamster kidney and the tumour induced by stilboestrol. There is evidence, however, that overall differences of structure of the proteins occur consistently between the normal and tumour tissue. This conclusion is in agreement with that of Cruft, Mauritzen and Stedman[14], who found evidence that the physical properties of histones from malignant cells exhibit pronounced differences from those of normal cells, although there was no difference in the amino-acid composition.

We wish to thank Prof. Alexander Haddow and Prof. F. Bergel for their advice and encouragement in the course of the work, and Dr. E. S. Horning, who also kindly supplied all the tissues used throughout this work. This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the British Empire Cancer Campaign, Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. # SIGNIFICANCE OF GLUTAMIC ACID IN METABOLIC PROCESSES IN THE RAT BRAIN DURING PHYSICAL EXERCISE

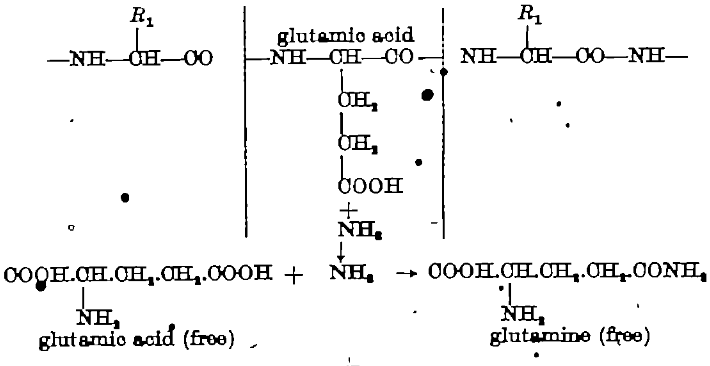
By Dr. R. VRBA

Institute of Industrial Hygiene and Occupational Diseases, Prague 2

PHYSICAL exercise is associated with an increased functional activity of large areas of brain, since, during physical exercise, impulses are sent to peripheral organs, signals come back from proprioceptors, and simultaneously the nerve centres are in action which co-ordinate the internal organs, the blood circulatory system, the respiration, etc., with active muscles. We consider the diffuse neuromuscular activity an appropriate model of the increased functional activity of the brain nervous tissue. The functional activity of the nervous tissue is always associated with the formation of ammonia[1]. In our previous experiments we found that during physical exercise the ammonia formed in the brain is bound in the form of glutamine[2]. Simultaneously with this process, the splitting of ammonia off amide bonds of proteins of the brain nervous tissue takes place[3]. On the basis of these experiments we assume that during functional activity of the brain associated with the performance of physical exercise, metabolic processes as shown in scheme (I)[2] take place in the brain nervous tissue.

This scheme is supported by the following facts: (1) during functional activity of rat brain nervous tissue, a decrease of the actual concentration of the amide group in the brain protein fraction occurs[3]; (2) as has been described many times, during functional activity of the nervous tissue ammonia is formed[1]; (3) during functional activity of the brain nervous tissue in association with physical exercise, an increase of the actual concentration of free glutamine in the brain takes place[2]; (4) functional activity of the nervous tissue is associated with structural changes in the nervous tissue proteins[3].

One of the further assumptions of this scheme is that with the increase of the concentration of free glutamine in the brain a decrease in the concentration of the free glutamic acid in the brain during physical exercise should take place. The correctness of this assumption has now been examined experimentally.



$$COOH.\underset{NH_2}{CH}.CH_2.CH_2.COOH + NH_3 \rightarrow COOH.\underset{NH_2}{CH}.CH_2.CH_2.CONH_2$$

(I)

The experiment was performed on 72 rats weighing 150–200 gm., which were divided into six experimental series. Each experimental series contained twelve rats of approximately the same weight and age. Each experimental series of twelve rats was divided into two groups of six animals. One group swam for 4½ hr. under conditions described previously[2]. The swimming served us as a model of diffuse neuromuscular activity. The second group served as controls. After the cessation of swimming, the rats both of the experimental and the control group were thrown into liquid air and frozen *in vivo*. The frozen brains of the experimental animals were dissected, homogenized to powder by crushing at low temperature and put in a weighed flask containing 100 ml. of 12 per cent trichloroacetic acid. Into a second flask the brains of animals of the control group were put in the same way. The wet weight of the brains was determined by differential weighing. The trichloroacetic acid was then filtered off, and the rest of the tissue was extracted three times with 50 ml. of 12 per cent trichloroacetic acid solution. From the combined trichloroacetic extract, after removal of glutamine and trichloroacetic acid, an aqueous solution of amino-acids contained in the acid-soluble rat brain fraction was prepared according to the method of Ansell and Richter[4]. This aqueous solution was used for the chromatographic separation of amino-acids. On the chromatographic paper, 15-$\mu$l. volumes of the aqueous amino-acid solution were applied, which corresponds to 30 mgm. of wet brain tissue. Under our conditions of chromatography, no desalting procedure was necessary.

As shown in the paper of Fischer and Dörfel[5], only one-dimensional chromatography is suitable for quantitative determination of amino-acids on paper. Amino-acids of the control and the fatigued group of one experimental series were applied on a sheet of filter paper Whatman No. 1, using always on one paper four samples of the control group of a series and four samples of the fatigued group of the same series, alternately. The amino-acids were separated one-dimensionally by repeated (10–12 times) descending chromatography with a butanol/acetic acid/water mixture[6]. After complete separation of amino-acids, which takes about a fortnight, the chromatogram was developed by ninhydrin, photographed on microfilm and the microfilm evaluated microphotometrically on a Soviet microphotometer (*MF-2*). For the separation and the quantitative evaluation of amino-acids, the method described by Keil[6] was used with slight modifications.

Fig. 1 represents a chromatogram of one experimental series (series No. 5). The sample of the experimental group is marked with the letter $N_1$ (first column from the left), next is the sample of the fatigued group, marked with the letter $P_1$ (second column from the left). Then follows the sample of the control group ($N_2$) and again a sample of the fatigued group ($P_2$). In the middle of the chromatogram, a sample of ovalbumin hydrolysate ($O$) is applied, the composition of which is known, and which is applied for the identification of amino-acids. To the right from the ovalbumin sample are again applied alternately the sample of the control and the fatigued group ($N_3$, $P_3$, $N_4$, $P_4$).

Fig. 2 gives a typical microphotometric evaluation (column $N_3$ and $P_3$ from chromatogram No. V) of our chromatograms. The 'spectra' of the free amino-acids of the control group are drawn with a full line,

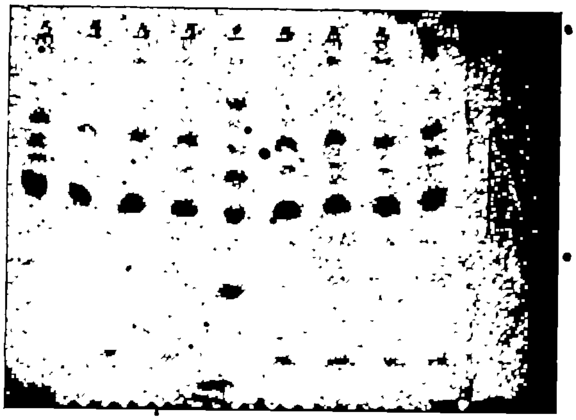


Fig. 1

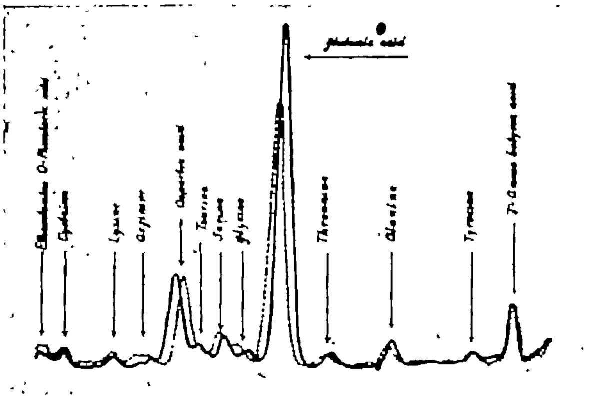

Fig. 2

and the dotted line corresponds to free amino-acids in the brains of the fatigued group of animals. Each maximum corresponds to one amino-acid, and the area below the maximum is proportional to the concentration of the respective amino-acid. The difference between the control and the fatigued group is shown by the fact that in the acid-soluble fraction of brains of the fatigued group the concentration of glutamic acid is always lower than in the control group. The curves were checked planimetrically. As to the rest of the amino-acids, their concentration either does not change during physical exertion, or minute variations upwards or downwards appeared, as is usually the case with biological materials. The concentrations of the free glutamic acid, however, were in all six experimental series lower in the brains of the fatigued animal group in comparison with the respective control group ($P < 0.01$). From each experimental series four parallel pairs of curves of the 'spectra' of amino-acids of both the control and the fatigued group were constructed on one chromatogram. The results fully confirm our previous assumption[2] that during the functional activity of brain nervous tissue in association with the performance of physical exercise a decrease of the concentration of free glutamic acid in the rat brain takes place. One of the effects of the participation of glutamic acid in this physiological process is the increase of the concentration of free glutamine[2]. A logical conclusion from this fact would be that during the restitution period (that is, during rest after physical exertion) a decrease of the glutamine concentration in the brain should take place. This assumption has been proved experimentally.

The experiment was carried out on eighty-four rats weighing 120–160 gm. each, which were divided into seven experimental series of twelve animals each. The twelve animals of one experimental series swam for 4½ hr. under the conditions described previously[2]. After the cessation of swimming, the twelve experimental animals were divided into two groups of six animals each. One group, the controls, was killed at once, the other group was killed after a rest period of 20 hr. Glutamine was determined in the average sample of brains of the fatigued and the rested group by the modified method of Richter and Dawson[1]. The results are given in Table 1.

The experimental results confirm that, during rest after physical exertion, a statistically significant decrease of the free glutamine concentration in the rat brain takes place. This result confirms, and

Table 1. Effect of Rest on the Free Glutamine Concentration in the Rat Brain

(Each number represents a pooled sample of six brains, determined in each case by four parallel determinations. The results are expressed in µmoles amido-N/gm. wet brain tissue*)

| Series | After 4½ hr. swimming (*A*) | After 4½ hr. swimming + 20 hr. rest (*B*) | Difference (*B* − *A*) | Difference in % |
|---|---|---|---|---|
| 1 | 12·4 | 9·6 | − 2·8 | − 22·6 |
| 2 | 7·95 | 7·75 | − 0·2 | − 2·6 |
| 3 | 7·6 | 7·2 | − 0·4 | − 5·3 |
| 4 | 9·7 | 8·35 | − 1·35 | − 13·9 |
| 5 | 8·5 | 8·0 | − 0·5 | − 5·9 |
| 6 | 11·1 | 10·8 | − 0·3 | − 2·7 |
| 7 | 11·8 | 9·1 | − 2·7 | − 22·9 |
| | | | − 1·18 ± 0·43<br>$P < 0·05$ | |

* The values are not corrected for the free ammonia. During physical exertion no changes of the concentration of free ammonia in the rat brain take place (ref. 2). Maximal error of the method is 2–3 per cent

completes at the same time our previous findings[2], that during physical exercise an increase of the actual concentration of the free glutamine in the rat brain takes place.

The question is raised, however, of the significance of the free glutamine in the brain during rest. The glutamine in the brain is not only the form in which ammonia is transported for excretion from the organism, but it has also another role[7]. In recent years, the great importance of glutamine for the synthesis of polypeptides and proteins has been clarified in a series of papers[8]. In one of our previous papers we examined the effect of physical exertion on the Kjeldahl-nitrogen concentration in the protein fraction of the brain. (By the term 'protein fraction' we understand the rest of the nervous tissue of the rat brain after extraction with trichloroacetic acid and removal of lipids by extraction with organic solvents[3].) The results of this experiment are given in Table 2.

Table 2. Effect of Physical Exertion on the Kjeldahl-Nitrogen Concentration in the Rat Brain Protein Fraction

| Series | Normal (*A*) | After 4½ hr. swimming (*B*) | Difference (*B* − *A*) |
|---|---|---|---|
| 1 | 1116·7 | 1108·4 | − 8·3 |
| 2 | 1002·6 | 931·1 | − 71·5 |
| 3 | 1072·8 | 978·1 | − 94·7 |
| 4 | 958·7 | 936·7 | − 22·0 |
| 5 | 958·6 | 987·6 | + 29·0 |
| 6 | 1040·3 | 1014·1 | − 26·2 |
| | 1024·9 | 992·7 | − 32·2 ± 18·1<br>$P < 0·1$ |

In the course of physical exertion, a decrease in the average concentration of Kjeldahl-nitrogen from 1024·9 µmoles/gm. to 992·7 µmoles/gm. of wet weight brain tissue took place. The difference was −32·2 ± 18·1 µmoles/gm. This decrease is not statistically significant, and we could therefore only state that, on the basis of these figures, we did not find a statistically significant decrease of the Kjeldahl-nitrogen in the brain protein fraction during physical exertion[3].

There is, however, a tendency towards decrease of the Kjeldahl-nitrogen during physical exertion. In six experimental series, each containing twelve experimental animals, a decrease of the Kjeldahl-nitrogen in the brain protein fraction occurred in five cases. We decided, therefore, to study this phenomenon further. Other experimental series were so arranged that all experimental animals were allowed to swim for 4½ hr. Some were killed immediately after cessation of this physical exertion, the others after resting for 20 hr. If the tendency to decrease in the actual concentration of Kjeldahl-nitrogen in the protein fraction of rat brain during physical exertion, as seen in Table 2, is not incidental, then we would expect the protein fraction of rat brain of animals rested after physical exertion to show an increase in the Kjeldahl-nitrogen concentration, in comparison with that of the brain protein fraction of rats killed immediately after physical exertion. The results of this experiment are shown in Table 3.

Table 3. Effect of Rest after Physical Exertion on the Kjeldahl-Nitrogen Concentration in the Rat Brain Protein Fraction

| Series | After 4½ hr. swimming (*A*) | After 4½ hr. swimming + 20 hr. rest (*B*) | Difference (*B* − *A*) |
|---|---|---|---|
| 1 | 889·3 | 939·3 | + 50·0 |
| 2 | 850·0 | 900·0 | + 50·0 |
| 3 | 872·9 | 935·7 | + 62·8 |
| 4 | 983·6 | 985·7 | + 2·1 |
| 5 | 960·7 | 986·2 | + 25·5 |
| 6 | 989·3 | 1064·3 | + 75·0 |
| | 924·3 | 968·5 | + 44·2 ± 10·8<br>$P < 0·01$ |

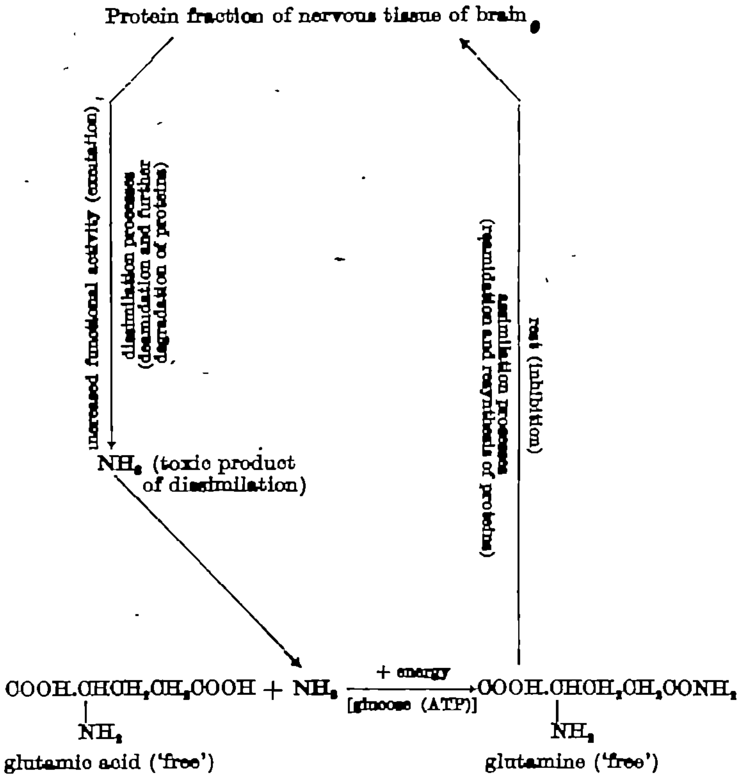
The method we used for Kjeldahl-nitrogen estimation was strictly checked, and it was found that the maximum error of estimation was less than 1 per cent

From Table 3 it is apparent that an increase of the Kjeldahl-nitrogen in the brain fraction of experimental rats takes place in all six series during rest after physical exertion. The difference (+ 44·2 ± 10·8 µmole Kjeldahl-nitrogen/gm. wet brain tissue) is statistically significant ($P \sim 0·01$).

On the basis of the results in Tables 2 and 3, we conclude that during the functional activity of the brain nervous tissue in association with physical exertion, a decrease of the Kjeldahl-nitrogen concentration in the rat brain protein fraction occurs, whereas during rest an increase takes place.

Recently it was shown, using $^{35}$S-methionine, that the metabolic activity of brain proteins is relatively high[9]. Similarly, the cytochemical studies of Hydén showed that the protein and polynucleotide content of the nervous tissue changes during functional activity of the nervous tissue[10]. Our experimental results also show that the metabolic activity of brain proteins is relatively high, and that the processes of functional activity of nervous tissue are associated with metabolic processes in the protein fraction of the brain nervous tissue. During increased functional activity, dissimilation processes are predominant in the protein fraction of the brain nervous tissue, whereas during rest, assimilation processes prevail in this fraction.

On the basis of experimental results given in this and the previous papers, we believe that the following scheme of the chemical processes in the brain provides a working hypothesis: (1) During the functional activity of the brain nervous tissue a degradation of nitrogen substances in the brain protein fraction takes place. One of the first processes indicating the participation of the proteins in the functional activity of the brain nervous tissue is the splitting of the amide-nitrogen off the polypeptidic chain of proteins of the brain nervous tissue. During these degradation processes, ammonia is formed; and the processes mentioned above may be the cause of the well-known fact[1] that the functional activity of the nervous tissue and the formation of ammonia are closely related. (2) Ammonia formed during the functional activity of the brain nervous tissue is a toxic product to the nervous tissue, and it is bound in the brain *in vivo* by the free glutamic acid. This process is manifested by the increase of the concentration of the free glutamine during increased functional activity of the brain nervous tissue in association with diffuse neuromuscular activity[2] and a decrease of free glutamic acid concentration. (3) The free glutamine formed during functional activity of the brain nervous tissue is not only a detoxication product serving for the excretion of ammonia; it is also the basis for the resynthesis of the high-molecular nitrogen-containing substances in the brain nervous tissue during rest. This is shown by the fact that during rest a decrease of the free glutamine in the brain takes place which is associated with the parallel increase in the concentration of Kjeldahl-nitrogen in the brain protein fraction. (4) The functional activity and the rest of the brain nervous tissue are chemically related as a cyclic process of degradation and resynthesis of the protein fraction of the brain nervous tissue. In this cyclic process, the free glutamic acid and the free glutamine occurring in the brain in molecularly dispersed form have an important role. The free glutamic acid has great significance in the final phase of the degradation process of the cyclic changes of brain nervous tissue proteins, as an intercepting link for ammonia, this being the final product of this degradation phase. During this process free glutamine is formed from the free glutamic acid, which is simultaneously an initial link for the phase of resynthesis. The free glutamic acid and the free glutamine represent in the brain a system lying at the turning point for degradation and resynthesis of the protein fraction of brain nervous tissue, and connecting the catabolic and anabolic processes in the brain nervous tissue. The increased functional activity of the brain is characterized by catabolic processes, the decreased functional activity (rest) by the predominance of anabolic processes in the protein fraction of the brain nervous tissue.



Protein fraction of nervous tissue of brain
increased functional activity (excitation)
dissimilation processes (desamidation and further degradation of proteins)
NH₃ (toxic product of dissimilation)
rest (inhibition)
assimilation processes (reamidation and resynthesis of proteins)
+ energy
[glucose (ATP)]
glutamic acid ('free')
glutamine ('free')

$$\underset{\displaystyle NH_2}{COOH.CHCH_2CH_2COOH} + NH_3 \xrightarrow[\text{[glucose (ATP)]}]{+\text{ energy}} \underset{\displaystyle NH_2}{COOH.CHCH_2CH_2CONH_2}$$

(II)

From the formulation of points 1 to 4 results our view of the unity and close relation of the processes of excitation and inhibition from the chemical point of view. During excitation, dissimilation processes in the brain nervous tissue are predominant, but simultaneously also synthetic processes are taking place. During inhibition, synthetic processes predominate, but simultaneously dissimilation processes also take place. The chemical basis of the processes of excitation and inhibition appears to us, in the light of our experiments, as a shift of the equilibrium to one side or the other.

Our findings are in good agreement with the conceptions of I. P. Pavlov, and provide concrete evidence supporting the hypothesis formulated by him in the following way: "The process of inhibition is probably associated with assimilation, similarly, the process of excitation is naturally associated with dissimilation"[11] (inhibition in Pavlov's terminology is understood as an active process).

We wish to emphasize, however, that the chemical basis of the process of excitation and inhibition is undoubtedly represented by a wide complex of chemical processes, and the scheme we have suggested can be only considered as a contribution to the partial clarification of these processes. Similarly, the participation of glutamic acid in the chemical processes associated with the functional activity of the brain nervous tissue cannot be limited only to the chemical process described above.

I wish to thank Mrs. Rosa Ehrmann, Mr. J. Karaus and Mr. J. Vesely for assistance in the experimental work.

## Carbon-13 Isotope Effects in the Decarboxylation of some Oxaloacetates

The effect of isotopic substitution on the rate of fission of carbon–carbon bonds has been the subject of many studies over the past eight years. The balance of the experimental evidence indicates that for some decarboxylation reactions the ratio of $^{14}$C- to $^{13}$C-isotope effects may not be readily accounted for by statistical rate-theory on the basis of changes in isotopic mass alone[1]. It has been suggested that apparently anomalous isotope-effect ratios may be due to some effect of carbon-13 nuclear spin[2]. In this connexion, it is of interest that some decarboxylation reactions have been found to be catalysed in aqueous solution by paramagnetic ions[3-5].

We have now measured the carbon-13 isotope effect in the decarboxylation of 'natural' oxaloacetic acid in aqueous solution at 25°, alone, and in the presence of diamagnetic yttrium ($Y^{3+}$) and paramagnetic dysprosium ($Dy^{3+}$) ions.

$$(M^{3+}), {}^{-}OOC.COCH_2 \,|\, {}^{12}COO^{-} \rightarrow {}^{-}OOC.COCH_3 + {}^{12}CO_2 \qquad (1)$$

$$(M^{3+}), {}^{-}OOC.COCH_2 \,|\, {}^{13}COO^{-} \rightarrow {}^{-}OOC.COCH_3 + {}^{13}CO_2 \qquad (2)$$

$M^{3+}$ represents $Y^{3+}$ or $Dy^{3+}$.

The effluent carbon dioxide was analysed with a Metropolitan-Vickers *MS*-2 mass-spectrometer, and the ratio of the rate constants for reactions (1) and (2) was calculated from the measurements of carbon-13 dioxide to carbon-12 dioxide ratios at 5 per cent and at 10 per cent decarboxylation (with the measured ratio for 100 per cent reaction).

CARBON-13 ISOTOPE EFFECTS AT 25°

| | Oxaloacetic acid ($p$H = 1) | $Y^{3+}$ oxaloacetate | $Dy^{3+}$ oxaloacetate |
|---|---|---|---|
| $100\left(\frac{k_{12-12}}{k_{12-13}} - 1\right)$ | 6 | 5 ± 1 | 10 ± 1 |

The mass-spectrometer was not used at its highest level of accuracy, but the above preliminary values show that there is a definite 'magnetic' isotope effect, well in excess of any probable error.

At $p$H = 1, in the absence of added trivalent ions, the carbon dioxide comes in approximately equal amount from undissociated acid and monovalent anion[6]. The isotope effects for these two species are not expected to differ greatly[6], and this is supported by the reasonable agreement with the isotope effect for yttrium oxaloacetate. The experiments in the presence of trivalent ions were so designed that decarboxylation was mainly due to oxaloacetate complexes[5]; thermodynamic association constants for yttrium and dysprosium oxaloacetates are nearly equal[7].

The carbon-13 isotope effects for oxaloacetic acid and for yttrium oxaloacetate are close to those previously observed for decarboxylation reactions, taking into account the observed dependence on temperature[6]. The carbon-13 isotope effect for dysprosium oxaloacetate is very considerably higher. The dysprosium ion is known to cause an acceleration in the rate of fission of $^{12}C-^{12}C$ bonds specifically by virtue of its unpaired 4*f* electrons[4,5]. A comparison of the isotope effects we have found shows that the paramagnetic dysprosium ion catalyses the fission of $^{12}C-^{12}C$ bonds about 4 per cent more strongly than the fission of $^{12}C-^{13}C$ bonds.

One possible interpretation of this 'magnetic' isotope effect is that carbon-13 nuclear spin – electron spin interactions are of the same order of magnitude as the electron spin – electron spin interactions produced at a greater distance by the paramagnetic ion. The effect of the paramagnetic dysprosium ion will then be greater on $^{12}C-^{12}C$ bonds than on $^{12}C-^{13}C$ bonds, where the carbon-13 nuclear spin effect will already be operative. Confirmation of this hypothesis will be sought in a series of similar experiments on carbon-14 isotope effects, carbon-14 having zero nuclear spin.

A full account of this work will be published in due course.

## Counting Tritiated Water at High Humidities in the Geiger Region

A METHOD for the direct counting of tritiated water in the Geiger region at high humidities would be most useful. Heretofore, tritiated water has been counted in the Geiger region at pressures less than 2 mm.[1]; or the water has been allowed to react with zinc[2], and the resulting hydrogen counted in a Geiger–Müller tube; or the water has been allowed to react with calcium carbide[3] or aluminium carbide[4] to produce acetylene, which could then be counted. Recently, Nilsson and Aniansson[5] developed a flow counter which would operate in the proportional region with high-humidity gas. They attributed their success to the use of gases such as ethane, propane or *n*-butane, which have ionization potentials lower than that of water vapour. I have succeeded in counting in the Geiger region with a high-humidity gas, a 1·3 per cent *iso*butane-in-helium mixture (Nuclear Chicago *Q*-gas) being used as the flow gas.

A brass counter 5¾ in. long and 1⅛ in. inside diameter was built. An 'Amphenol 82–805' 'Teflon'-insulated connector in the closed end of the brass tube served as the high-voltage connector, and also carried a brass rod ⅛ in. in diameter and 1⅜ in. long to which was attached the anode—a tungsten wire 4 mils in diameter and 1¼ in. long. An opening ⅜ in. in diameter and 2⅜ in. from the top of the tube served as a window over which a source of activity could be placed. The metal planchet carrying the activity was sealed to the tube with 'Apiezon-*Q*'. The window looked directly into the middle of the sensitive volume of the tube. The flow gas entered through a copper tube at the top and left through a copper tube at the

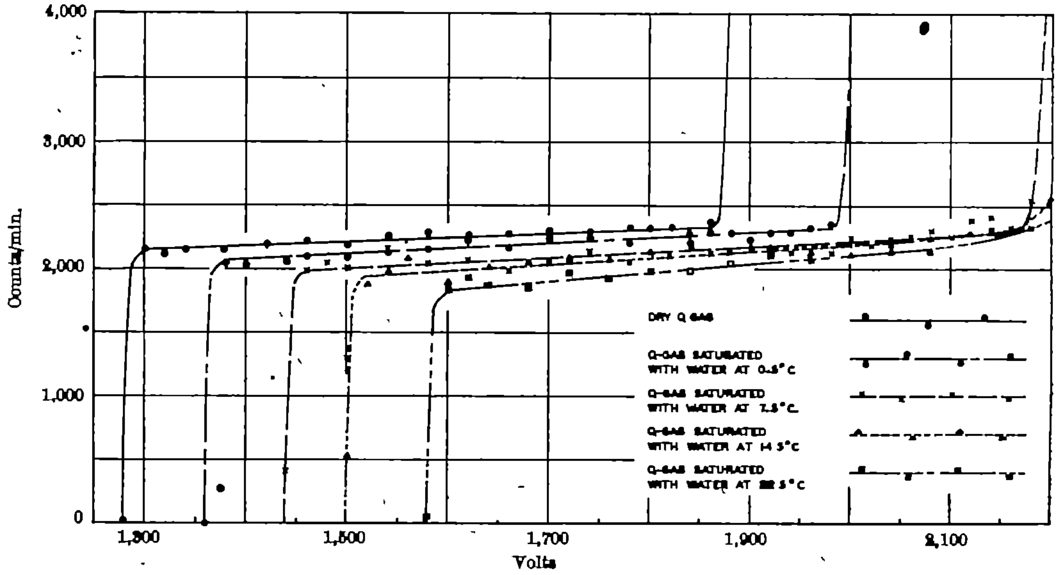

Fig. 1. Geiger plateaux for Q-gas containing various amounts of water vapour

bottom of the counter. The bottom of the brass tube was sealed by a metal plate and 'Apiezon-Q'.

The Q-gas left the storage cylinder through a reducing valve, entered a coil of copper tubing immersed in a Dewar flask, entered a saturator also in the same Dewar, entered another copper coil in a second Dewar, entered the counter, and then escaped through a bubbler which indicated the rate of gas flow. The first Dewar flask was filled with water at the temperature at which it was desired to saturate the gas. The second Dewar contained water at a degree or so below room temperature and served to warm the gas-plus-water vapour back to room temperature.

Sodium-22 in the form of sodium chloride was used as a source of activity. The source contained on a small aluminium planchet was placed over the window of the counter. Table 1 gives the temperatures of the water in the saturator, the vapour pressure of water at these temperatures, and the corresponding relative humidities at a room temperature of 33° C.

Table 1

| Dewar 1 temperature, ° C. | Vapour pressure of water (mm. mercury) | Per cent relative humidity (room temperature, 33° C.) |
|---|---|---|
| 0·5 | 4·75 | 12·6 |
| 7·5 | 7·78 | 20·6 |
| 14·5 | 12·38 | 32·3 |
| 22·0 | 19·82 | 52·6 |

Fig. 1 shows the Geiger plateaux obtained with the 'dry' Q-gas and with the gas containing varying quantities of water. The slopes of these plateaux increase as the water vapour in the gas increases. The slope for Q-gas alone is 1·64 per cent per 100 V. and that for Q-gas at a relative humidity of 52·6 per cent is 3·64 per cent. All of the plateaux are long, ranging from 600 V. to 400 V. The downward displacements and the changes in the slopes of the plateaux are probably caused by a change in the sensitive volume of the tube as a result of the presence of water vapour. The water dipoles apparently modify the electric field between anode and cathode.

0·01 ml. of tritiated water having a specific activity of 10 mc. per ml. was diluted to 10 ml. in a volumetric flask. 5 ml. of this solution was diluted to 10 ml. in a second volumetric flask, etc. A series of five solutions, each differing from the previous one by a factor of ½, was thus prepared. About 3 ml. of a given solution was placed in the saturator, which was then put in the Dewar and brought to 0° C. by means of an ice–water mixture. The voltage on the scaler was set at 1,660 V. Q-gas was allowed to flow through the system and counts were taken over successive 5-min. intervals until the counting-rate became constant within the statistical error involved. This process took about one hour. The results are plotted on a relative basis in Fig. 2. The points all lie on a straight line and intersect the zero con-

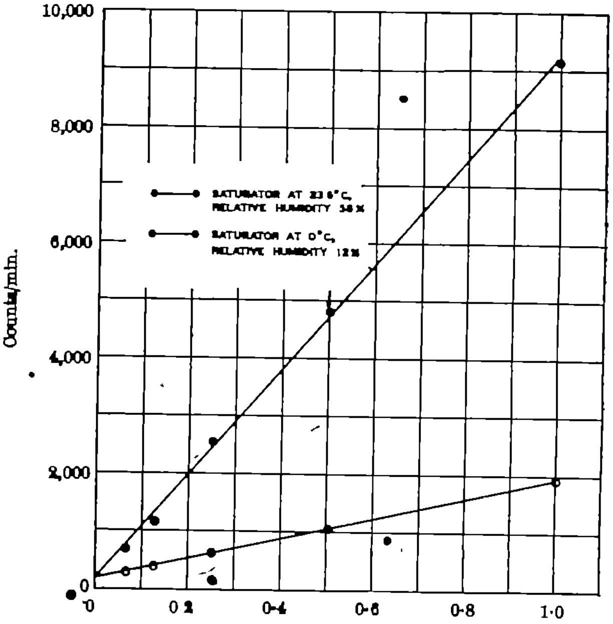

Fig. 2. Linear response of the counter as a function of the concentration of tritiated water

centration axis at 175 c./min., which agrees well with the measured background of 162 c./min., as it should. Another set of results for this series of tritiated water solutions was obtained with the water in the saturator maintained at 23·6° C.; these, which are also plotted in Fig. 2, show much more scatter than do the results obtained at 0° C., because the temperature was not maintained at exactly 23·6° C. but fluctuated about this value.

The results obtained demonstrate the feasibility of counting in the Geiger region at high relative humidities. They point to the almost certain possibility of absolute counting for tritium in the form of THO. The results also indicate the possibilities for the design of counters specifically to be used at high humidities. The paper by Cockcroft and Curran[6] is particularly suggestive in this light.

More complete and extensive results will be presented elsewhere as the work progresses. I wish to thank Dr. W. H. Johnson of Purdue University for his helpful comments.

## Measurement of Tritium in Water Samples

THE concentration of tritium in water samples has been measured by a new method which is both simple and rapid. The beta-rays of very low energy which are emitted by tritium are very difficult to count because of their inability to penetrate the windows of conventional Geiger counters. It has therefore been the practice for some time to introduce the tritium in various chemical combinations into the interior of a counter.

The method to be described consists of introducing the tritium in the form of water vapour as part of the filling of an internal gas counter. Any tritium atoms disintegrating inside the sensitive volume of the counter give rise to counts, and from the observed count-rate the number of tritium atoms present is evaluated.

The water vapour at saturation vapour pressure is introduced and the filling completed with 10–15 cm. pressure of a standard argon–alcohol mixture. An accurate measure of the pressure of the water vapour is obtained from the temperature and tables of saturation vapour pressures.

The argon–alcohol mixture is prepared beforehand in the normal ratio of 9 to 1, and stored in a 5-litre glass bulb at an initial pressure of 30 cm. Absolute alcohol is used and the argon is purified by flowing through a charcoal trap at liquid-nitrogen temperature.

Counters manufactured by Twentieth Century Electronics, type GA.10.M., are used. The outer envelope is made of glass and the cathode is of steel. The sensitive volume of the counter is about 50 c.c.

Using these counters in conjunction with an external quench unit, type 1014A, consistent plateaux are obtained with a length of more than 400 V. and a slope less than 2 per cent per 100 V. The threshold voltage is about 1,400. The efficiency, as compared with a 10-cm. argon filling and using an external source of cobalt-60, is 98 per cent. The counters are not sensitive to light. If, after counting at a rate of 10,000 per min., the counter is pumped only for a few minutes, the residual contamination produces about 200 counts per min. This is easily removed by flushing two or three times with pure water vapour and if necessary heating slightly.

The normal working pressure of the vacuum apparatus is 1 micron, which can easily be obtained with a single-stage rotary vacuum pump and a liquid-nitrogen trap.

## The Reduction of Vitamin $B_{12}$

Two distinct reduction products of vitamin $B_{12}$ have been described in the literature, by Diehl and Murie[1] and by Boos, Carr and Conn[2]; we shall refer to these as I and II respectively. They differ in their method of preparation, and have widely different absorption spectra in the visible and ultra-violet, but may both be re-oxidized to vitamin $B_{12a}$ by exposure to air, and from polarographic and titrimetric evidence both are claimed to contain divalent cobalt.

Compounds with spectra closely resembling that of I may be obtained by the action of a variety of reducing agents on vitamin $B_{12}$. Diehl and Murie employed catalytic hydrogenation; but cysteine in alkaline solution, lithium boron hydride, heating in 96 per cent ethanol for 12 hr. at 100° C. in a nitrogen atmosphere, and chromous acetate in aqueous solution, all give similar products, at least initially.

Hydrogenation, using palladium on barium sulphate as catalyst, readily continues beyond the stage represented by I, which in consequence cannot be obtained in a pure state by this method. For this reason, vitamin $B_{12a}$ is obtained in yields of only 60–70 per cent on re-oxidation (Boos *et al.*[2]; Brockman *et al.*[3]). Hydrogenation finally results in visually colourless products with ill-defined ultra-violet absorption; but intermediate compounds with diminished visible colour may also be obtained. On exposure to air, these give brown compounds with spectra somewhat similar to that of I, but which are altered by *p*H changes. They also form reddish cyanide derivatives. They are characterized by rather broad bands in the 435–450-mμ region, and the benziminazole of the nucleotide is no longer co-ordinated to the cobalt, as indicated by the sensitivity[4] of the spectra in the 280 mμ region to *p*H. A very similar sequence is obtained by reduction with lithium boron hydride in aqueous solution. Reduction with chromous acetate in aqueous solution (*p*H *c.* 5), however, was found to give a solution of I which was stable indefinitely in a hydrogen atmosphere, even in the presence of excess reducing agent. Its spectrum (see Fig. 1) is very similar to that given by Diehl and Murie, and re-oxidation to vitamin $B_{12a}$ appears to be substantially quantitative.

Boos *et al.* obtained II by reduction of vitamin $B_{12}$ in ethylenediaminetetraacetate buffer at *p*H 9·5 with chromous chloride. They observed, however, that the product obtained by the addition of one equivalent of the chromous salt was brown, whereas II has a characteristic grey-green colour (see Fig. 1). We have reduced vitamin $B_{12}$ in a similar manner, by addition of small amounts of solid chromous acetate to a de-aerated solution of the vitamin in a hydrogen atmosphere, and have found that in ethylenediaminetetraacetate buffer at *p*H 3 the reduction product is exclusively I. At *p*H 9·5 II results if an excess of the reducing agent is used; but I appears as an intermediate product, and with smaller amounts of chromous salt the reduction may be stopped at this stage. The sequence may be reversed by cautious aerial oxidation of a solution of II, which thus appears to be a more highly reduced form of vitamin $B_{12}$ than I.

Both I and II are formed as readily from vitamin $B_{12a}$ as from vitamin $B_{12}$, and II may also be prepared from a solution of vitamin $B_{12}$ (as the purple dicyanide) in dilute potassium cyanide solution at *p*H 9·5. Its formation does not therefore depend on the presence either of cyanide ion or of ethylenediaminetetraacetate. The oxidation of I by cyanide as described by Diehl is questionable.

The ready re-oxidation of both I and II to vitamin $B_{12a}$ suggests that in both cases the organic part of the molecule has not been significantly affected, and that the changes have concerned the state of oxidation of the cobalt only. In this case the differences between the spectra of I and II are remarkable. That of II even suggests increased conjugation of some kind, possibly resulting from a rearrangement of double bonds, accompanied by release of the benziminazole from co-ordination, as is indicated by increased resolution of the benziminazole fine-structure.

In this connexion it might perhaps be suggested here that the spectrum of vitamin $B_{12}$ may be better accounted for by the addition of one extra double bond to the structures given as alternatives by Crowfoot *et al.*[5] and by Todd and co-workers[6]. The possibility of such an additional double bond is mentioned by Crowfoot *et al.*, and the two alternative structures would then be capable of resonance. The evidence, based on chlorination, in support of the structures as given does not seem sufficiently weighty to rule out completely this possibility. Activated positions susceptible to chlorination still remain in the structures with six conjugated double bonds, and although a further increase in conjugation by elimination of hydrogen chloride cannot then occur so obviously, the spectrum of reduction product II suggests that a long-wave shift of the vitamin $B_{12}$ spectrum may not necessarily require the introduction of additional unsaturation into the molecule.

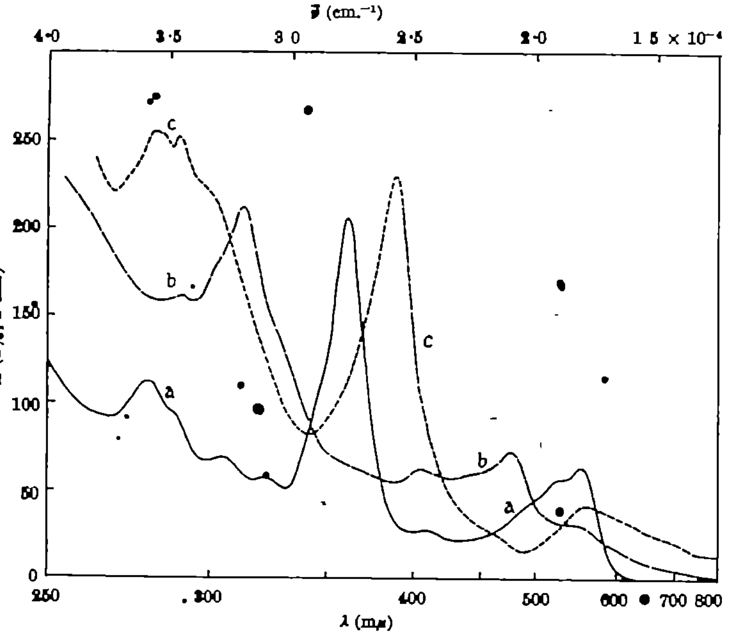

Fig. 1. (*a*) ———, vitamin $B_{12}$ in water; (*b*) — — —, brown reduction product (I), (*c*) - - - - - - -, grey-green reduction product (II). The abscissa is linear in wave-number ($\bar{\nu}$), and the ordinate in extinction coefficient, E(1%, 1 cm.)

## Genetic Control of some Serum Proteins in Normal Humans

IN a previous communication[1], one of us described the grouping of normal individuals into three groups (I, II*A* and II*B*) on the basis of differences in their serum proteins. A full account of the starch-gel electrophoretic method used for demonstrating these differences and a discussion of the validity of the consequent groupings are now in the press[2]. In these two papers it was suggested that the serum group of a given individual might be fixed and determined by genetic factors.

The distribution of the serum groups in forty-one normal adults unrelated by consanguinity or marriage was found in the earlier work to be: group I, 8; group II*A*, 21; and group II*B*, 12; that is, approximately 1 : 2 : 1. No significant difference was observed in the distribution in males and females. These results suggested to us that the serum group of an individual is controlled by two autosomal genes with incomplete dominance, the frequency of occurrence of the two genes being approximately equal. If this hypothesis is correct, individuals in group I have one type of homozygous combination of genes, those in group II*A* have the heterozygous combination, and those in group II*B* have the other type of homozygous combination of genes.

Table 1

| Types of mating | Expected proportions of offspring | | |
|---|---|---|---|
| | Group I | Group II*A* | Group II*B* |
| I × I | 1·0 | — | — |
| I × II*A* | 0·5 | 0·5 | — |
| I × II*B* | — | 1·0 | — |
| II*A* × II*A* | 0·25 | 0·5 | 0·25 |
| II*A* × II*B* | — | 0·5 | 0·5 |
| II*B* × II*B* | — | — | 1·0 |

We have therefore commenced a study of families to investigate the hypothesis, and this communication reports on the results obtained so far from eighteen families. It is our intention to increase the number of families to at least fifty; but the results have been sufficiently definite to warrant an interim report on the present smaller number.

Table 1 shows the possible types of matings and the expected frequencies of the offspring among the three serum groups for each mating.

Table 2 shows the results we have obtained from the eighteen families. In every case the offspring were found to have serum groups in complete agreement with the genetic theory, and the observed and expected distribution of the offspring among the three serum groups for all the matings observed were not significantly different. Consequently, on the basis of the eighteen families so far studied, we suggest that the genetic hypothesis here described is correct, and that the serum group of an individual is indeed controlled by two autosomal genes with incomplete dominance.

It will be noted that we have not observed matings of the types I × II*A* and I × II*B*, although the frequencies of occurrence of the three serum groups in unrelated individuals led us to expect five or six of these matings out of eighteen. This may well be a reflexion of the smallness of our present sample; but the possibility of an incompatibility between certain of the groups with a consequent decrease in the fertility of the respective marriages is receiving our attention.

Through the kindness of Dr. Bruce Chown (Children's Hospital, Winnipeg) a determination of the previously known blood groups [*ABO*, *MNS*, *CDE* (*Rh* factor), *K* (Kell), *JK* (Kidd), *Fy* (Duffy), *Le* (Lewis) and *Lu* (Lutheran)] has been made for all individuals comprising the eighteen families so far studied. No direct correlation of any of these blood groups with the new serum groups has been observed. Consequently the medico-legal aspects of the new inherited serum groups will be appreciated, especially as the two genes which control the serum groups occur with approximately equal frequencies.

Table 2

| Types of mating | Total matings | Total offspring | Offspring serum groups | | | | |
|---|---|---|---|---|---|---|---|
| | | | | I | II*A* | II*B* | |
| I × I | 1 | 2 | Observed | 2 | 0 | 0 | |
| | | | Expected | 2 | 0 | 0 | |
| I × II*A* | 0 | 0 | Observed | – | – | – | |
| | | | Expected | – | – | – | |
| I × II*B* | 0 | 0 | Observed | – | – | – | |
| | | | Expected | – | – | – | |
| II*A* × II*A* | 8 | 20 | Observed | 8 | 8 | 4 | $\chi^2 = 2\cdot4$ |
| | | | Expected | 5 | 10 | 5 | $P = 0\cdot3$ |

## Production of 'O Inagglutinability' in Erythrocytes coated with Typhoid Vi and O Antigens

STRAINS of *Salmonella typhosa* resistant to agglutination by *O* antibody, although containing the characteristic *O* antigen, were observed by Felix and Pitt to be considerably more virulent for mice than strains which were readily agglutinated by *O* antibody. This '*O* inagglutinability' of virulent typhoid cultures was eventually shown by these workers to be associated with the presence of an additional component, the Vi antigen, which had a pronounced effect on the behaviour of the *O* antigen[1].

The phenomenon of '*O* inagglutinability' which led to the discovery of the Vi antigen is the most distinctive and also the most vulnerable property of the Vi antigen of *S. typhosa*. During the past decade, analogous phenomena have been described in certain coliforms and shigella. It therefore seems likely that it is of rather frequent occurrence among enteric species.

The fact that the presence of Vi antigen prevents the agglutination of typhoid bacilli by *O* antibody has been interpreted by some to mean that the Vi antigen is a more superficially located component covering or blanketing the *O* antigen, whereas others favour the view that the Vi antigen so affects the bacterial surface that, by steric hindrance, union of the *O* antigen, also at the cell surface, with its own antibody is prevented.

During the course of studies on the interaction of purified bacterial polysaccharides and erythrocytes, we observed that the phenomenon of '*O* inagglutinability' could readily be reproduced experimentally. Thus when purified Vi and *O* antigens were adsorbed on washed human or sheep erythrocytes either simultaneously or consecutively in either sequence, increasing concentrations of the Vi antigen resulted in a progressive reduction in the agglutinability of the erythrocytes by typhoid *O* antiserum. On the other hand, the Vi agglutinative properties of the suspension remained unaffected.

The Vi antigen employed was isolated from *Escherichia coli* 5396/38. This acidic, highly polymerized polysaccharide is believed to be composed of units of N-acetylamino-hexuronic acid[2]. In its immunological specificity it is indistinguishable from the Vi antigen of *Paracolobactrum ballerup*, *S. typhosa*, and *S. paratyphi* C[3]. The *O* antigen was isolated from the 0901 strain of *S. typhosa* and characterized as a protein-free phosphorylated lipopolysaccharide possessing the immunological and endotoxic attributes of the intact organism[4]. The technical details of sensitization of red cells with these products and their reactions in the hæmagglutination procedure have been described elsewhere[5].

It was reported earlier that erythrocytes could be sensitized with a number of purified bacterial polysaccharides either simultaneously or consecutively without discernible interference of one antigen with the activity of any other[4]. However, the concentration of antigens employed (generally 1 µgm. per ml. of 1 per cent red-cell suspension) was only slightly in excess of the amount required for maximal agglutinative activity. In the present study it was observed that when erythrocytes were treated with *O* and Vi antigens, suppression of agglutination by typhoid *O* antibody occurred when the concentration of Vi antigen employed was 10 µgm. or more per ml. of a 1 per cent red-cell suspension. The results of a typical experiment are given in Table 1. Washed erythrocytes were treated with various concentrations of the purified antigens, singly, consecutively or simultaneously, the treated cells washed three times to remove unadsorbed antigen, made up to a 1 per cent suspension, and set up with *O* and Vi antibacterial sera. Inspection of this arrangement shows that concentrations of Vi antigen sufficient to bring about maximal hæmagglutination by Vi antibody have no discernible effect on the typhoid *O* reactivity of these erythrocytes. However, when the amount of Vi antigen employed for sensitization is increased to 10 µgm., a significant reduction in reaction with typhoid *O* antibody occurs. This diminution of *O* agglutinability becomes more pronounced as the quantity of Vi antigen is increased, and at the highest level tested (100 µgm.) the agglutination titre with *O* antiserum was reduced from 1 : 2,560 to 1 : 80. These results indicate that the extent to which erythrocytes treated with *O* antigen react with specific antibody is inversely related to the concentration of Vi antigen to which the cells were exposed.

These findings are in harmony with the early observations of Felix[7] that *O* inagglutinable strains of *S. typhosa* contain the maximum amount of Vi antigen, whereas strains which are readily agglutinated by *O* antibody contain considerably less. Recently, a comparison of the Vi antigen content of the well-known *O* inagglutinable *Ty2* and fully *O* agglutinable '58' strains of *S. typhosa* showed that, in terms of immunogenic potency and the quantity of Vi antigen actually isolated, the *Ty2* strain contained five to ten times as much Vi antigen as the *O* agglutinable strain '58'[8].

Table 1. '*O* INAGGLUTINABILITY' IN BACTERIA AND IN ERYTHROCYTES CONDITIONED BY VI ANTIGEN

| Agglutinating systems | Agglutinating antisera (reciprocal of end titres) | |

* Per ml. of 1 per cent red-cell suspension.

Thus the phenomenon of *O* inagglutinability, so well known in typhoid serology, has been in large part duplicated in an experimental model employing erythrocytes and purified Vi and *O* antigens. The interference with *O* agglutination has been shown to be related to the concentration of Vi antigen employed to treat the red cells. These observations provide supporting evidence for the thesis that *O* inagglutinability is an indicator of high or maximal content of Vi antigen in typhoid cultures. They may also be pertinent to the controversy concerning the relative positions of the Vi and *O* antigens on the bacterial surface. The fact that the suppression of *O* agglutinability by Vi antigen occurs regardless of the order in which the Vi and *O* antigens are adsorbed on erythrocytes suggests that '*O* inagglutinability' is not attributable to the 'covering' of the *O* antigen by Vi, but rather is brought about by steric hindrance or a non-specific stabilization of the cell by certain physico-chemical properties peculiar to the Vi antigen. Suppression of agglutination is not restricted to the typhoid *O* antigen adsorbed on red cells, since other bacterial polysaccharides applied to red cells are similarly affected by the Vi antigen. The non-specificity of this blocking action by Vi antigen is further attested in experiments (unpublished results) in which we found that adsorption of Vi antigen on human erythrocytes, in addition to affecting the reaction of other bacterial antigens adsorbed on the red cell, as here described, also suppresses or interferes with blood-group agglutinability, that is, antigens native to the red cell.

## Fat Production by Inositol-deficient Yeast

THE growth of a yeast (*Saccharomyces cerevisiae*) and a bacterium in mixed culture in a defined medium containing an abnormally low concentration of growth factors has been studied by Challinor and Rose[1], who observed a number of inter-relationships between the two organisms under these conditions. During the continuation of this work, growth of the yeast in a medium in which the concentration of a single growth factor (inositol) was reduced below the normal level was studied, and interesting changes in the morphological and physiological characters of the yeast were observed. Thus, microscopical examination revealed that the deficient cells formed large aggregates and were more granular than normal cells. These differences were clearly seen after two days growth and became more marked during further incubation. After about three days, the deficient cells were obviously unhealthy in appearance and were easily ruptured, for example, by pressing the coverslip lightly once only. The ease with which rupturing took place increased on further incubation, and after five days very little pressure indeed was required to release the cell contents. A large part of the material so released was oily in nature, and the small droplets coalesced to form large globules which gave typical staining reactions for fats when treated with sudan III and with osmic acid. Normal cells behaved very differently, considerable pressure being required to cause rupture, and then only a proportion of the cells were broken, releasing very little fatty material.

Smith[2] has studied the role of inositol in the nutrition of *S. carlsbergensis*, and he observed that under conditions of inositol-deficiency the yeast grew abnormally, forming aggregates; but he did not comment on the strength of the cell wall or upon fat formation. In view of (1) the apparent high proportion of fatty substances in our deficient cells as compared with the normal cells, and (2) the ease with which these substances were liberated, it was decided to measure the fat production by inositol-deficient cells. Fat production was followed in media containing normal and deficient amounts of inositol, and with ammonium monohydrogen phosphate as the source of nitrogen. The effect of variation of the carbon–nitrogen ratio was studied by reducing the amount of ammonium phosphate to 50 per cent and to 37·5 per cent of the amount in the normal medium. This medium contained: glucose (6 per cent), ammonium hydrogen phosphate (0·237 per cent), adenine, guanine and uracil each 10 μgm./ml., D-biotin 2·2 mμgm./ml., calcium-D-pantothenate 2·5 μgm./ml., thiamine hydrochloride 2 μgm./ml., pyridoxin hydrochloride 2·5 μgm./ml., nicotinic acid 2 μgm./ml., pteroylglutamic acid 0·1 μgm./ml., salts, and inositol 10 μgm./ml. In the deficient media the amount of inositol was reduced to only 0·6 μgm./ml.

The yeast was grown in culture bottles (Glaxo pattern, 2·5 litres capacity; 300 ml. medium per bottle) at 30° C., harvested after five days and the cells ground in a Griffiths tube and dried overnight; the fatty substances were then extracted with 40–60° light petroleum (five consecutive extractions). The yield of fatty substances from the inositol-deficient cells (274 mgm.) was 67 mgm. (24·5 per cent) as compared with only 7·9 mgm. (1·6 per cent) from the normal cells (489 mgm.).

These extractions were carried out at room temperature, and the amount of fat taken out by each extraction was weighed separately so that the ease of extraction from cells grown in the different media could be ascertained. Results indicated that this procedure gave satisfactory extraction from the inositol-deficient cells grown in the medium containing the full amount of ammonium phosphate; but the cells grown in each of the two media containing the reduced amounts of ammonium phosphate did not liberate fat quite so easily and extraction was not quite complete. The yields of fat from the cells grown in each of the latter two media were 60 mgm. (24·7 per cent) and 54 mgm. (22·6 per cent) respectively and, having regard to the above considerations, these yields would not appear to be materially different from that obtained from inositol-deficient cells grown in the medium containing the full amount of ammonium phosphate.

If fat is to be produced commercially from micro-organisms, ease of extraction would be a factor of importance. In view of the ease with which the fat was released from the inositol-deficient yeast, it was decided to extract the cells directly with light petroleum without previous grinding. The yield of fatty substances thus obtained was 59 mgm. (22·3 per cent of the dry weight of the cells), that is, approximately 91 per cent of that extracted from cells which had been ground before extraction. The difference in ease of extraction of the ground and unground cells was therefore small, and it seems likely that it would be narrowed still further by using a higher temperature for the extraction.

## Autoradiographic Localization of Iodine-131 in the Salivary Glands of the Hamster

THE concentration of iodide in human saliva is known to be many times greater than the concentration in the plasma[1]. We have identified the structures associated with a similar iodide-concentrating mechanism in the submaxillary and parotid salivary glands of the hamster. Radioiodide (500 μc. of iodine-131) was injected intraperitoneally into an adult hamster. One hour later, with the animal under ether anæsthesia, the right submaxillary and parotid glands, together with a piece of muscle, were removed and dropped immediately into a vessel containing difluorodichloromethane cooled in liquid air. The frozen tissues were crushed in a mortar cooled in liquid air, and the fragments freeze-dried at − 40°. Contact autoradiographs were then made from sections 7μ thick by a method already described[2]. The concentration of iodine-131 was also measured in portions of the opposite salivary glands, in muscle, and in plasma and saliva removed immediately after the samples were taken for autoradiography. Table 1 shows the ratio of the concentrations of iodine-131 in tissue and plasma in each of the samples.

Table 1

| Tissue | Concentration ratio |
|---|---|
| Submaxillary gland | 5·3 |
| Parotid gland | 1·7 |
| Muscle | 0·4 |
| Saliva | 28·0 |

In sections of the submaxillary gland stained with hæmatoxylin and eosin the ducts could be distinguished by their palely staining cells, and the areas of blackening in the autoradiograph were found to be confined to the ducts. Under high magnification it is possible to distinguish the proximal (acinar) parts of the duct system from the distal ones. Proximally, the lumen is inconspicuous and the lining cells are tall with basal nuclei, whereas the distal part has a wider lumen and is lined by cuboidal cells with central nuclei. Fig. 1*a* shows a branched duct cut longitudinally, with a blood vessel adjacent to it. The intensity of blackening in the autoradiograph (Fig. 1*b*) is no greater over the acini than that over the blood vessel. Blackening is most intense over the proximal portion of the branched duct and over other ducts in which the proximal part has been cut transversely. Over some of the distal portions of ducts the intensity of blackening is only a little greater than that over blood vessels or acini.

In sections of the parotid gland stained by the periodic acid – Schiff method, two types of ducts can be distinguished (Fig. 2*a*). The proximal portions have a narrow lumen and are lined by dark flat cells, whereas the distal portions have a wide lumen and are lined by large pale cuboidal cells. The pattern of blackening in the autoradiograph (Fig. 2*b*) is seen to correspond with the distal ducts. The intensity of blackening over the acini and over the proximal ducts is no greater than that over blood vessels. The concentration of iodine-131 in the parotid ducts was much less than that in the submaxillary ducts, as judged by the times of exposure needed to give the same degree of blackening in the two sections.

Autoradiographs made from frozen sections of muscle treated in the same way as the sections of submaxillary and parotid glands showed no blackening. Autoradiographs made from frozen sections of submaxillary and parotid, treated with water after alcohol fixation, showed no blackening.

From the pattern of blackening described above, we conclude that the mechanism responsible for concentrating iodide in the saliva of the hamster is present in certain parts of the duct system of the submaxillary and parotid glands. The slight blackening over some of the distal ducts of the submaxillary gland could be explained by the presence of radioactive saliva in the lumen formed farther up the duct, since iodine-131 was shown to be highly concentrated in the saliva. However, we cannot exclude the possibility that the distal parts of the ducts are also able to concentrate iodide feebly. The blackening over the proximal ducts of the submaxillary gland cannot be due to iodine-131 concentrated in the acini and carried down in the saliva. The concentration of iodine-131 in the plasma of the hamster does not begin to decrease until more than an hour after an intraperitoneal injection. If, therefore, it were continually secreted at a high concentration by the acini and carried down the ducts, the intensity of blackening over the acini would have been at least as great as that over the ducts. By an analogous argument the blackening over the distal parts of the parotid ducts cannot be due to iodine-131 concentrated in the acini or in the Schiff-positive ducts. From the degree of resolution in these sections it is impossible to decide whether the blackening is due to iodine-131 in the cells lining the ducts, in the lumen, or in both. Therefore we cannot say whether the high concentration of iodine-131 in the saliva is due to a direct secretion from the duct cells or to selective reabsorption of water and other solutes from the saliva as it passes down the duct.

## Occurrence of the Alga *Gloeocapsa* in the Air

THE pollen and fungus spore content of the air has been investigated extensively during recent years in connexion with respiratory allergy and crop diseases. Less is known of other constituents of the air spora. The occurrence of unicellular algæ in the air or in air-borne dust has been demonstrated by several investigators[1].

In quantitative studies of the air spora, we have observed the regular occurrence of a blue-green alga identifiable microscopically as belonging to the Chroococcaceae, probably *Gloeocapsa* (Fig. 1). This is a minute unicellular alga forming loose colonies on moist surfaces, either inland or on the sea-shore. The origin of these air-borne *Gloeocapsa* colonies is at present unknown; they do not appear to be lichen soredia, because most of the colonies observed were free from fungus hyphæ. The mechanism by which they get into the air is also obscure.

Data are available from three centres at each of which air was sampled almost continuously during June 30–July 13, 1954, at a height of 2 metres above ground-level, using the Hirst[2] automatic volumetric spore trap, in which the solid particles in a measured volume of air are deposited in a continuous trace on a slowly moving microscope slide. The deposit on our slides was examined microscopically at distances along the trace corresponding to two-hourly intervals. The areas scanned provided estimates of the number of particles in 12 litres of air for each 2-hr. period. The highest concentration of the alga was observed at Thorney Island, Hants, where an average of 110 colonies per cubic metre of air was recorded over the period of observation. On the roof of the Botany Department, Imperial College of Science and Technology, South Kensington, and in an arable field at Rothamsted Experimental Station, Harpenden, Herts, the average concentration was only 1/20 of that at Thorney Island. Table 1 shows the frequency of occurrence of *Gloeocapsa* colonies in the 12-litre samples, and also the mean and maximum concentration at each centre.

Table 1. OCCURRENCE OF *Gloeocapsa* COLONIES IN THE AIR DURING JUNE 30–JULY 13, 1954

| Site | No. of 12-litre samples with *Gloeocapsa* | | Concentration per cubic metre of air | |
|---|---|---|---|---|
| | Present | Absent | Average | Maximum |
| Thorney Island, Hants | 55 | 95 | 110 | 800 |
| South Kensington, London | 5 | 134 | 7 | 100 |
| Rothamsted, Harpenden, Herts | 7 | 137 | 5 | 100 |

At Thorney Island the air-borne *Gloeocapsa* colonies averaged about eight cells each. There was a marked diurnal periodicity of occurrence: the maximum at 23.00 hr. averaged 210 colonies per cubic metre, and the minimum, between 04.00 and 13.00 hr., averaged about 30 colonies per cubic metre. Their occurrence was not obviously related to the state of the tide. At Rothamsted and South Kensington, concentrations are known to have been somewhat higher during mid-June 1954 than they were during the period described when sampling was also in progress at Thorney Island.

The concentrations recorded so far are small in comparison with those normal for pollen or fungus spores. They are nevertheless high enough at Thorney Island to indicate that air dispersal may be important in *Gloeocapsa*. With an average concentration of about 800 cells per cubic metre of air for at least three weeks, this organism warrants further study as a potential allergen, especially as the cells of *Gloeocapsa* are embedded in a thick sheath of mucilage.

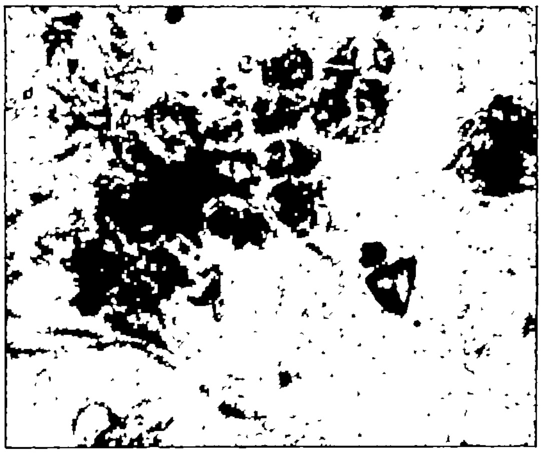

Fig. 1. Group of cells of *Gloeocapsa* type from air sampled at Thorney Island, 21.00 hr., July 8, 1954. × 500 approximately

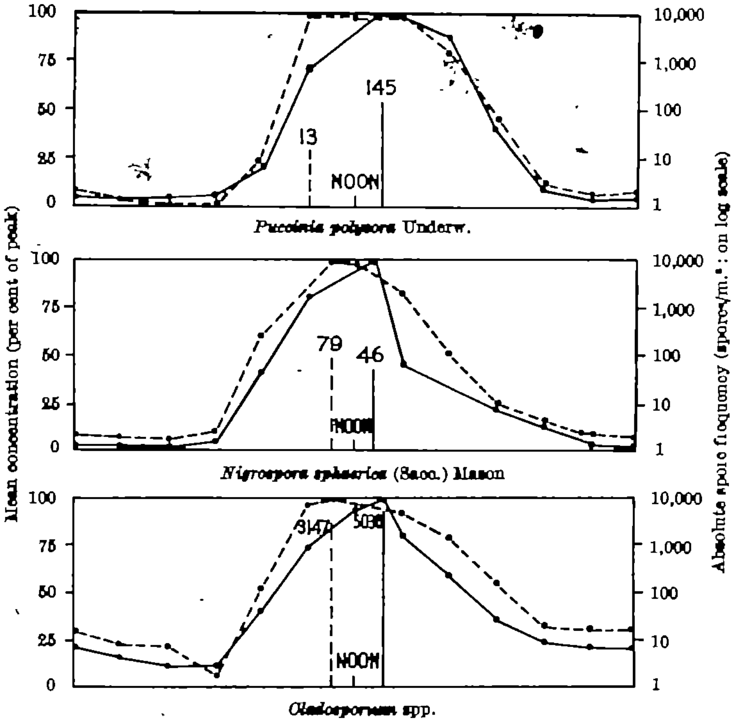
## Seasonal Changes in Three Common Constituents of the Air Spora of Southern Nigeria

FLUCTUATIONS in the air spora have been studied in a temperate climate by Hirst[1,2] and others. Less is known of the changes which occur in the tropics. The study of these changes is valuable in assisting the prediction and analysis of epidemics of plant disease due to air-borne fungi.

The observations described below were made at the Federal Department of Agricultural Research, Ibadan, Western Region, Nigeria. The station is at lat. 7° 23′ N., long. 3° 50′ E. at an elevation of 600 ft. above mean sea-level and lies on the edge of the lowland rain forest belt. The annual rainfall is 45–50 in. and typically there is a dry season from December to March and a rainy season from April to November, with a short break during the first half of August. Further details of the vegetation are given by Keay[3] and of the climate by Brooks[4].



*Puccinia polysora* Underw.

*Nigrospora sphaerica* (Sacc.) Mason

*Cladosporium* spp.

Fig. 1. Mean diurnal periodicity curves of three common constituents of the air spora at Ibadan, Nigeria. ———, wet-season results; - - - -, dry-season results

The air spora was sampled with an automatic volumetric spore trap sited in the middle of a 7-acre field of close-mown grass. This field is centrally situated within 850 acres of mixed annual and perennial crops. The orifice of the trap was two metres above ground-level.

It was found necessary to modify the methods described by Hirst[2], in order to overcome the effects of high temperature and humidity. The best primer of the microscope slide was 'Solvar 3515'. When applied in a thin film and allowed to dry in a desiccator at laboratory temperature, this priming film was least prone to wrinkling, which has proved to be a troublesome artefact. Ordinary 'Vaseline' when used as an adhesive was found to have too low a melting point, resulting in distortion of the trace. A satisfactory adhesive was B.D.H. Paraffinum mollo album, with the addition of 1½ per cent ceresin wax (congealing point 60° C.). This mixture was suitable for use in the high day temperatures experienced and retained good optical properties.

Slides were exposed for periods of 24 hr. and fluctuations in spore concentrations determined by counting 14 mm. traverses at right angles to the long axis of the trace, at distances corresponding to 2-hourly intervals. Counts were expressed as numbers of spores per cubic metre of air. The following spores were studied during both wet and dry seasons:

(*a*) *Puccinia polysora* Underw., a leaf rust of maize the uredospores of which are found in considerable numbers during both wet and dry seasons. (In separating *P. polysora* from other uredospore constituents on the traces, phase contrast was found to be advantageous in recognizing spore numbers and other spore characters.)

(*b*) *Nigrospora sphaerica* (Sacc.) Mason, a dry rot of maize. A common component of the air spora at all times of the year.

(*c*) *Cladosporium* spp., abundant during both wet and dry seasons.

Diurnal periodicities were obtained from counts made over the rainy period April–June 1954, and during the dry months of December 1954–March 1955. In Fig. 1, for comparative purposes, the mathematical treatment is that employed by Hirst[2], periodicities being expressed as percentages of the peak geometrical mean concentrations. The means were calculated from counts made over eighty-seven days in the case of *Puccinia polysora*, and fifty days for both *Nigrospora sphaerica* and *Cladosporium* spp. Corrections for the trapping efficiency of the volumetric trap were applied to *Puccinia polysora* and *Nigrospora sphaerica*. The efficiency of the trap is defined by Gregory[3].

To illustrate the differences in position and size of the peak concentrations of the curves in the wet and dry seasons, the values have been given as the mean peak concentrations of spores per cubic metre of air. This figure was calculated from the average of the daily values of the peak concentration during the wet and dry seasons respectively, and is represented on a logarithmic scale by the vertical lines in Fig. 1.

The general forms of the wet and dry season curves are similar, but peak concentrations occur at an earlier hour of the day during the dry season. This may be due in part to higher temperatures and lower humidities during the dry season, the fall in humidity with rising temperature being more rapid than in the wet season, and consequently minimum relative humidities occur earlier in the day. Highest concentrations of the three spore types mentioned are found under conditions of high temperatures and low humidities coinciding with the peaks of the curves. The wet season curves of *Puccinia polysora* and *Cladosporium* spp. agree generally in form with those obtained by Hirst in Britain for the uredospore group and species of *Cladosporium* respectively.

The absolute values of spore concentrations illustrate that the wet season numbers of *Puccinia polysora* are much higher than those of the dry season, and that *Cladosporium* spp. concentrations are high in both seasons. *Nigrospora sphaerica* is higher in the dry season. The variations in spore numbers depend largely on the availability of hosts in the two seasons as well as on climatic factors, and this is being further investigated.

A correlation of fluctuations in the atmospheric spore load with temperature and humidity values indicates that these variables are two of the more important causal factors influencing the seasonal change in the concentration and diurnal periodicity of the spores mentioned. This will be discussed more fully elsewhere.

Acknowledgments are due to the Director, Federal Department of Agricultural Research, Nigeria, for making facilities for these observations available. I am indebted to Dr. W. R. Stanton for sponsoring

the project and to Dr. J. M. Hirst, Rothamsted Experimental Station, for many helpful suggestions.

## A Statistical Information Theory of Visual Thresholds

It is well known that, for constant stimulus duration, the visual threshold intensity, $I$, is a function of the stimulus area $A$. In the case of absolute thresholds it has been generally accepted that: (i) for areas up to about 6′, $AI =$ constant (Ricco's law); (ii) for areas between about 6′ and perhaps 20°, $AI^2 =$ constant (Piper's law).

It seems reasonable to regard the absolute threshold as a special case of the differential threshold. It is then important to discover whether these relations in fact hold for the differential case. Brindley[1] has shown that Piper's law holds for differential thresholds where the test field is discriminated against a large field of constant area. Ricco's law is also found to hold for blue light, optical effects making it difficult to test for other colours. Piper's law for differential threshold where the background area is large and fixed has been formulated:

$$\frac{\Delta I}{I} = \text{const.} \sqrt{\frac{1}{A}} \qquad (1)$$

We find, by using various small background areas, that the more general case where either area is variable may be written, at least approximately,

$$\frac{\Delta I}{I} = \text{const.} \sqrt{\left(\frac{1}{A_1} + \frac{1}{A_2}\right)} + C \qquad (2)$$

This would give the Weber–Fechner law, $\Delta I/I = C$, for very large areas $A_1$ and $A_2$, which would make $\left(\frac{1}{A_1} + \frac{1}{A_2}\right)$ negligibly small.

We also find that this may be further generalized to cover low intensities in the region of breakdown of the Weber–Fechner law by adding a small constant thus:

$$\frac{\Delta I}{I + k} = \text{const.} \sqrt{\frac{1}{A_1} + \frac{1}{A_2}} + C \qquad (3)$$

The value of $k$ in terms of equivalent intensity we estimate at about 0·04 ft. l. For the absolute threshold, when $I = 0$, we should then have $\Delta I/k = C$ when the areas are large.

It appears that these, and perhaps other threshold and summation phenomena, may be described in terms of statistical information available in neural information channels. If we suppose that the area $A$ inspected is to be regarded as a set of $n$ independent observations, where $n$ is approximately proportional to $A$, and that each of these observations is subject to random variation through noise in the system, then for $\Delta I$ to be detected against $I$, in some fixed proportion of the number of trials (for example, an 80 per cent experimental criterion), we must have

$$\frac{[(r + \Delta r) - r] - C}{\sqrt{\left(\frac{1}{A_1} + \frac{1}{A_2}\right) V}} = \text{constant} \qquad (4)$$

where $(r + \Delta r)$, $r$, are the mean neural pulse-rates corresponding to intensities $I + \Delta I$, $I$, and $V$ is the variance of neural pulse-rate over the sample.

We have introduced the constant $C$ to explain the fact that few false positives occur in threshold experiments. Without some criterion of difference greater than zero, we should expect about 50 per cent false positives. The proportion of false positives may change with the observer's attitude, or 'set', indicating that $C$ may vary within limits. It is tempting to regard $k$ as arising from the internal noise present in the system, and to think of the absolute threshold as the case where the signal is to be distinguished against noise background.

If, as seems possible from electrophysiological data, $r$ is proportional to $\log (I + k)$, (4) reduces to (3) above for $\Delta I$ somewhat less than $I + k$, and we expect this to hold for relatively small values of $\Delta I$ even when $I = 0$, that is, for absolute thresholds. In the latter case, as the test area diminishes, however, and the value of $\Delta I$ consequently increases, the approximation $\Delta I/k$ used for $[(r + \Delta r) - r]$ is no longer valid, and the more accurate expression $[\log (k + \Delta I) - \log k]$ is required. For $A_2$ large, (4) can then be written

$$1 + \frac{\Delta I}{k} = \exp\,(C + \alpha\sqrt{1/A}),$$

writing $A$ for $A_1$ and denoting the constant involved by $\alpha$.

For very large $A$, the terms containing $A$ are negligible; therefore

$$1 + \frac{\Delta I}{k} = \text{const., or } \Delta I = \text{const.} \qquad (5)$$

For smaller $A$:

$$1 + \frac{\Delta I}{k} = \exp C\,(1 + \alpha/\sqrt{A})$$

or

$$\sqrt{A}\ \Delta I = \text{const.} + \text{const.} \sqrt{A} \qquad (6)$$

For even smaller $A$:

$$1 + \frac{\Delta I}{k} = \exp C \left(1 + \frac{\alpha}{\sqrt{A}} + \frac{\alpha^2}{2A} + \ldots\right) \qquad (7)$$

It thus appears that Ricco's and Piper's laws might be regarded as the different approximations to the logarithmic equation which can be used at different levels. The expression (7) appears to fit Willmer's[2] data satisfactorily. We are undertaking experiments to determine the various constants involved.

Mr. R. T. Leslie, Mr. E. R. F. W. Crossman and Dr. G. S. Brindley have been most helpful in discussing these and related ideas.

## Ascorbic Acid Content of Baobab Fruit

In the course of investigations into the nutritional value of traditional African foodstuffs, samples of the fruit of the baobab (*Adansonia digitata* L.) were taken for analysis. This tree, which is particularly noteworthy for the massive girth which its boll eventually attains, is widespread in the low-veld areas of Southern Rhodesia, and the pulp or matrix surrounding the seed in the fruit capsule is commonly chewed or sucked by the indigenous population, or made into a pleasant acidic drink, thus giving rise to the colloquial name of 'cream of tartar' tree.

While there appears to be some difference of opinion regarding the composition of the pulp[1], I have found no recent references in the literature regarding its nutritional value, and it was therefore decided to carry out ascorbic acid assays.

Samples of fruit, which had been collected by the inhabitants, were taken from a kraal in the Kariba gorge area of the Zambesi valley. The fruit was broken open and the seeds and pulp removed. The pulp was scraped from the seeds and ground to give a fine yellow-white powder passing through a B.S.S. No. 60 sieve.

The moisture content was determined and the pulp assayed for ascorbic acid by the 2 : 6-dichlorophenolindophenol visual titration method, as originally described by Bessey and King[2], and also by the 2 : 4-dinitrophenylhydrazine method of Roe and Oesterling[3], in this case determining reduced ascorbic acid, dehydroascorbic acid and diketogulonic acid. In both cases, the technique described by the Association of Vitamin Chemists[4] was followed.

The figures obtained on the pulp were as follows :

| | |
|---|---|
| Indophenol method : | 328 mgm. ascorbic acid/100 gm. |
| 2 : 4-Dinitrophenylhydrazine method: | 307 mgm. ascorbic acid/100 gm. |
| Moisture content : | 11·8 per cent |

Fairly reasonable agreement between the methods suggested that no appreciable amounts of interfering substances were present, and that the bulk of the vitamin was present in the reduced form.

The relatively high concentration of ascorbic acid present in the pulp suggested that further investigations be carried out, as the fruit is available where fresh fruit and vegetables are normally difficult to obtain. Further samples of baobab fruit were therefore obtained, in this case from the Sabi Experimental Station. Fruit was collected from ten trees, and the pulp obtained from the fruit of each tree was bulked and prepared for analysis as with the previous sample. No attempt was made to differentiate between the degrees of ripeness of the different fruit capsules.

The analytical figures obtained from the fruit pulp were as follows :

| | Ascorbic acid (mgm./100 gm.) | Moisture (per cent) |
|---|---|---|
| Minimum | 175 0 | 10 0 |
| Maximum | 445 4 | 13·1 |
| Mean | 306·2 | 10·9 |

The results confirmed the view that the baobab fruit is an important source of ascorbic acid ; and, in fact, the concentration of this vitamin in the baobab is one of the highest in any food in Southern Rhodesia.

Further investigations are in progress to establish the optimum ripeness for maximum ascorbic acid content, and also the stability of the vitamin on keeping, as the fruit is likely to remain on the tree for long periods before dropping.

## 'Self-Cure' in Nematode Infestations of Sheep

Earlier studies with sheep infested with *Haemonchus contortus* or with *Trichostrongylus colubriformis*[1–3] showed that the 'self-cure' phenomenon was caused by the intake of infective larvæ by sheep rendered hypersensitive as a result of previous infestations. The hypersensitive reaction was evidenced by a transient rise in blood-histamine within four days, by the development of skin-sensitivity to an antigen prepared from larvæ and by the development of œdema in the portion of the alimentary tract infested.

To obtain more direct evidence about the 'self-cure' reaction, selected sheep were anæsthetized by intravenous injection of 'Kemithal', which does not disturb infestations with *H. contortus*, the abomasum was exposed by laparotomy, massive doses of exsheathed larvæ were injected into the abomasum, and the reaction of the organ was observed for several hours.

In two worm-free lambs, which had not been exposed to infestation previously, the abomasum remained flaccid and normal for the whole period of observation. In two hypersensitive sheep infested with *H. contortus*, the abomasum showed increased peristalsis and segmentation within 10 min. of injection and, within 1 hr., was pale and œdematous and had contracted in diameter. The reaction commenced to subside in 1½–2 hr. Both sheep showed 'self-cure' ; in one the worm egg-count fell from 3,500 eggs per gm. of fæces to 0 in four days, and in the other, from 3,600 eggs per gm. to 400 in seven days. There was no increase in blood-histamine within 4 hr. of the injection of the larvæ. The abomasum was collected from two other hypersensitive sheep at the height of the reaction after the injection of larvæ. No deviation from normal values of histamine could be demonstrated in extracts of the abomasal wall, although the presence of œdema was confirmed by histological examination.

The reaction of several sheep, resistant to *H. contortus*, was examined in the same way and was found to be similar to that of the infested sheep.

It was also reported previously[3] that the intake of *H. contortus* larvæ produced 'self-cure' both of an infestation with the same species or with *T. colubriformis* which infests the duodenum. Further work showed that the intake of *H. contortus* larvæ will also cause 'self-cure' of infestations with other abomasal parasites such as *Ostertagia circumcincta* and *T. axei*, and that the intake of larvæ of these two species will cause 'self-cure' of infestations with *H. contortus* or with *T. colubriformis*.

The direct observation of the abomasum of hypersensitive sheep after the injection of exsheathed larvæ provides further support for the hypothesis that there is a change in environmental conditions at the time of the 'self-cure' reaction. The effect of the intake of larvæ of one species of nematode upon existing infestations with other species appears to depend upon their respective location in the alimentary tract, and again suggests a local rather than a systemic reaction. Antigenic material from larvæ in the abomasum could pass readily to the small intestine, whereas similar material from the small intestine could not pass readily to the abomasum.

## Polygenic Inheritance in *Neurospora*

ASCOSPORES of *Neurospora crassa* two to three times the normal size occur in many strains, though the frequency is low, probably less than one per thousand ascospores. A particular cross made in this laboratory produced an abnormally high frequency of giant ascospores (about 3·4 per cent), and since a number of these germinated and gave good cultures, a study of the phenomenon has been initiated.

Crosses between the cultures derived from these giant spores gave 11·4 per cent giant ascospores, and selection was started from one of these. In each generation giant spores were selected and cultures derived from them were set up as crosses. The successful crosses provided the next generation of ascospores. The response to selection is illustrated in Fig. 1, the frequency of giant ascospores in each generation being based on a sample of more than five hundred ascospores.

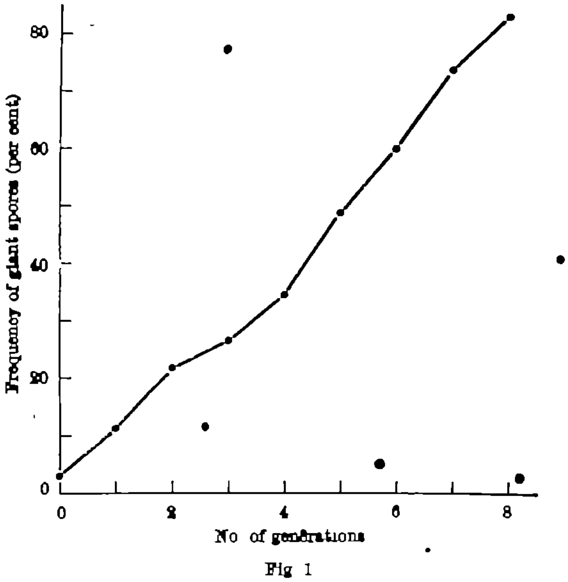

Fig 1

It should be pointed out that the classification into 'normal' and 'giant' spores is arbitrary. Both types vary, and during the course of the experiment the average size of both classes has increased. However, the great majority of asci gave either four 'giant' or eight 'normal' ascospores, and this results in a definitely bimodal size distribution. Selection has also changed the number of spores maturing in the asci. At the beginning of the experiment most asci contained eight mature, 'normal' spores; in the few asci which gave four 'giant' spores, only one spore matured, the rest of each ascus aborting. In later generations, asci with two, three and four mature 'giant' ascospores occurred. By the eighth generation the frequency of asci containing four mature 'giant' spores approached one per perithecium, and asci containing eight mature 'normal' spores were rare. No asci have been seen with more than four 'giant' spores. A few asci have been seen with spores of both types.

In the third generation, reciprocal crosses were made with a wild-type strain. The resulting asci were all normal. Thus the eight-spored character is 'dominant' to the four-spored, and the size of ascospore and type of ascus apparently depend on nuclear and not cytoplasmic factors.

A further cross was set up between a fifth-generation culture and a wild type. Again all the resulting asci contained eight spores, although the ascospores were rather plumper than the usual wild type. Cultures were derived from a number of these ascospores and crosses set up between them. In this way, twenty-six fertile *F*1 crosses were obtained and samples of ascospores from each of them classified. The results were:

| Frequency giant spores (%) | < 1 | 1–1·9 | 2–2·9 | 3–3·9 | 4–4·9 | 5–5·9 | 6–6·9 | 9–9·9 |
|---|---|---|---|---|---|---|---|---|
| No. of crosses | 13 | 3 | 3 | 2 | 1 | 2 | 1 | 1 |

The wide range of frequencies of giant spores from these crosses indicates that a considerable number of genes affecting the frequency of giant spores differentiate the selected and wild-type strains. The steady response to selection also indicates a polygenic character.

Additional evidence is provided by a cross between two strains from the third generation of selection. A normal eight-spored ascus from this cross was dissected in the usual manner into the four different spore pairs. The resulting four cultures were designated 1, 2, 3 and 4 and the four possible crosses were set up between them. The results were:

| Cross | Giant spores (%) |
|---|---|
| 1 × 3 | 12·2 |
| 1 × 4 | 17·0 |
| 2 × 3 | 18·1 |
| 2 × 4 | 21·1 |

It seems clear that segregation of polygenes affecting the frequency of giant spores occurred during the formation of the dissected ascospores.

One further phenomenon deserves mention: out of 110 giant spores which have so far been cultured, four have been self-fertile and presumably heterozygous for the mating-type alleles. Other markers are being introduced in order to discover if heterozygosity of other loci occurs in these strains.

The analogy between these strains and *N. tetrasperma* is obvious. Dodge[1] showed that in crosses between *N. sitophila* and *N. tetrasperma* the resulting asci were all eight-spored, and that continued backcrossing to *N. tetrasperma* restored the four-spored ascus character. It will be of considerable interest to see if the present low incidence of homothallic giant spores increases in the future generations of selection. In any event, it seems possible that further investigation of these strains may afford some evidence concerning the usually accepted origin of *N. tetrasperma* from an eight-spored form[2].

These strains may prove of experimental value in that they permit the study of a polygenic character in an organism in which ordered tetrads may be isolated. A further advantage is that all generations of a selection experiment may be preserved, since the ascospores remain viable for several years.

## Widespread Distribution of Mutant Alleles (t-Alleles) in Populations of Wild House Mice

FOLLOWING the proof that mutant changes at one locus ($t$) occur rather frequently in laboratory stocks of mice kept in the balanced lethal condition[1] $T/t^n$, we turned our attention to the problem whether such mutations are to be found also in wild populations. In the laboratory we had detected such mutations only in stocks which already contained a $t$-allele at this locus; stocks containing $T$ (brachyury = short tail) had been under continuous observation in the laboratory since 1932, but no occurrence of mutation to a $t$-allele (revealed by the tailless condition $T/t^n$) had been detected. Seven different $t$-alleles were detected and isolated[1] by testing the rare normal-tailed exceptions which were found after inbreeding the balanced-lethal tailless stock $T/t^1$. All such exceptions proved to be $t^1/t^x$, $t^x$ being a new allele at this locus. This suggested that $t^x$ had arisen either by recombination or rearrangement at the complex locus $t$ (Dunn, 1954) or that $t^1$ had induced mutation to a new allele. The fact that the new mutants were different from $t^1$ and from each other and that no recombination gametes containing the normal allele (+) were found was taken as evidence against the recombination hypothesis. The locus thus appeared to be unstable in the balanced lethal laboratory stocks. A question of interest was whether there was any evidence of this in wild populations remote from the few laboratories at which $t$-alleles were maintained.

The first tests of this point[2] showed decisively that $t$-alleles are normal components of some wild populations in the United States. Samples of mice caught in the wild were tested by mating them in the laboratory to a standard testing stock $T/+$ (brachy). Some wild mice when so tested produced, in addition to the expected brachy ($T/+$) and normal offspring, tailless offspring which, on further testing, proved to be $T/t^n$ and gave rise to new tailless balanced lines $T/t^{w1}$, $T/t^{w2}$, $T/t^{w3}$ and $T/t^{w4}$. The first three of these alleles were different from each other and from previously known $t$-alleles; the fourth was indistinguishable from a previously known allele $t^0$. Thus these first wild populations to be tested revealed a variety of alleles, as had the laboratory stocks.

Such tests have now been extended to include samples, usually small ones, from seventeen American populations. In addition, one Japanese population has been tested at the National Institute of Genetics of Japan by crossing with brachy testers ($T/+$) sent from our laboratory and a $t^w$ allele found in three animals. Of these eighteen populations, twelve contained animals heterozygous for a $t$-allele. Each occurrence of tailless offspring from a new population is given a number in the order of discovery. This does not necessarily indicate that the $t$-allele thus revealed is new and different from the others; this can be proved only by crossing balanced lethal lines, each derived from a different population, and such tests have been only partially completed. Of the newer alleles $t^{w5}$ (N.Y. 2) is lethal and different from $t^0$, $t^1$, $t^9$, $t^{w1}$ and $t^{w3}$; $t^{w6}$ (Florida 1) is lethal and different from $t^0$, $t^1$, $t^{12}$, $t^{w1}$; and $t^{w3}$, $t^{w5}$ and $t^{w6}$ cannot be distinguished by the usual test of viability at birth of the compound $t^{w5}/t^{w6}$. The hypothesis is being tested that this compound, which if found should have a normal tail, dies during embryogeny. $t^{w7}$ (Texas 1) is viable, hence different from $t^{w5}$, $t^{w6}$ and all previously known lethals, although its difference from other viables ($t^3$, $t^7$, $t^8$, $t^{11}$, $t^{13}$ and $t^{w2}$) cannot be directly tested. $t^{w8}$ (Virginia 1) is viable, hence different from any of the lethals. Occurrences $t^{w9}-t^{w14}$ have not yet been tested. These are as follows: $t^{w9}$ (Radford, Virginia) viable; $t^{w10}$ (Misima-sen, Japan); $t^{w11}$ (Storrs, Connecticut); $t^{w12}$ (Oakland, California); $t^{w13}$ (El Paso, Texas); $t^{w14}$ (Norwich, Vermont). It is already clear that not all alleles found in the wild are the same, and that many wild populations are polymorphic for this locus.

No single population has been proved not to carry a $t$-allele, since all the negative samples are quite small.

In the populations shown to contain a $t$-allele, the frequency of heterozygotes is very high. Of forty-seven animals tested from such populations, twenty-seven have proved to be heterozygous $+/t^w$. This does not include an extensive sample of ninety-two mice from one such population ($R3$), tested after eight years of inbreeding in the laboratory, in which fifty-two mice were heterozygous; their retention in such high frequency shows that evolutionary forces of some magnitude must oppose their extinction. One of these forces is the altered segregation ratio $t^w$ : + in males, in which the $t^w$ gamete is regularly favoured[3] by ratios of 0·8–0·9. The other may be selection in favour of $+/t^w$, and this is being tested experimentally. A preliminary experiment[4] suggests that $+/t^w$ males may be more fertile than $+/+$.

Many problems remain to be studied with this material. The ubiquity of $t$-alleles in wild populations is taken as proof of their evolutionary significance and justification for further study. Experiments now in progress are designed to test: (1) whether new alleles arise by mutation directly from the normal allele of wild $+/+$ mice (this event has never been detected in laboratory stocks); (2) whether the adaptive value of $+/t^w$ heterozygotes in wild populations differs from that of $+/+$; (3) whether any single wild population contains more than one variety of $t$-allele (no such instance has yet been noted); (4) whether the presence of a particular allele, or the absence of any such allele, bears any relation to the geographical or ecological situation of the population.

This work was carried out at Nevis Biological Station, Irvington-on-Hudson, New York, and since June 1, 1955, under contract $AT$(30–1–1804) U.S. Atomic Energy Commission. Many persons were concerned with collecting mice in the wild and others

with testing them in the laboratory. The co-operation of the former will be acknowledged in more extensive reports. The work depended very much on the skill in handling wild populations in the laboratory of Prof. W. C. Morgan, jun. (now at South Dakota Agricultural College), at the initiation of the experiment, of Mrs. Joan Suckling and Mary Anne Dann during its continuation, and most recently of Dr. Louis Levine, Andrew D. Beasley, Frank Burnett and Robert E. Stephenson, of the Nevis Laboratory.

## An Instrument for measuring Soil-Moisture Deficit

The estimation of residual available soil moisture should be an essential part of irrigation practice. Penman's method[1], based on meteorological observations. gives excellent results ; but in its present form it is somewhat cumbersome for use by commercial growers. Various alternative methods are available ; for example, measured evaporation from an open water surface may be expressed as potential evapotranspiration by means of a suitable conversion factor[1]. Garnier has measured evapo-transpiration directly using a standard grass surface[2]. There is, however, a need for a simple device which will integrate rainfall and evaporation measurements and give a reading expressed as soil-moisture deficit.

We have devised a combined rain-gauge and evaporimeter which ultimately may prove suitable for use by growers for day-to-day control of irrigation. It would also provide valuable data if installed in meteorological stations. The instrument is intended to be placed in a growing crop, so that it collects rain and irrigation water in a common receiver ; an evaporation surface, consisting of an unglazed ceramic disk, draws its water supply by capillarity from this receiver. Successful operation of the instrument depends upon correct adjustment of the ratio between the area of the collecting surface and the area of the evaporating surface. The total effective area of the evaporating surface is therefore determined by comparison with a free water surface. This is expressed in terms of area of soil completely covered by plants, using Penman's conversion factor (0·8 for south-east England, March–August). The instrument is then constructed so that the area of its collecting surface equals the area of its evaporating surface thus expressed in terms of plant-covered soil. It is necessary to provide means of adjusting the effective area of evaporating surface to compensate for differences in rate of water-loss between wet soils and dry soils, and between soils completely covered by plants and those only partially covered. An overflow is provided in the receiver at a level corresponding to field capacity, so that any rain which falls when the instrument is indicating field capacity is collected separately and gives a measure of the amount of drainage which has taken place through the soil. The water supply to the evaporating surface is so arranged that when the instrument is indicating wilting point, the water-level in the receiver is just below the level of the outlet, thus cutting off the supply and preventing further evaporation.

When the instrument is correctly adjusted, the amount of water in the receiver at any time corresponds to the amount of water remaining in the soil, so indicating directly the current soil-moisture deficit.

Many workers are carrying out experiments to determine the maximum permissible deficit at various growth stages of the major crop plants. The results of such experiments will enable this instrument to be used for deciding when to irrigate, in addition to indicating how much water is required to restore the soil to field capacity.

## Index of Translations of Foreign Scientific Material

The editorial article in *Nature* of November 19 raises once more the problem of how to ensure that foreign scientific material is economically translated and made available. The index of unpublished scientific translations maintained by Aslib, and covering the principal countries of the Commonwealth, is, I believe, one step in the right direction. May I appeal to readers of *Nature* to help make the index more effective by arranging, whenever possible, for details of partial or complete translation, made or about to be made by their organizations, to be notified systematically to Aslib ? The details required are : author, name of periodical, volume, issue number, inclusive pagination, date and translated title, as well as the form of translation (for example, typescript, microfilm, etc.), whether it is complete, partial or a summary, whether it can be bought or borrowed, and the name and address of the holding organization.

Many inquirers now systematically check with Aslib before starting a translation. Their intention to undertake the translation, if one is not known to exist, is recorded at once, so that it is sometimes possible to suggest a joint task with expenses shared to a subsequent inquirer. Last year (the third year of operation) the cost of 137 translations, representing perhaps some £3,000 and possibly unwelcome delays as well, was saved by the index ; the figure will doubtless be increased considerably as more firms and institutions collaborate.

The language barrier, however, is only one of many problems in the dissemination of knowledge. Paradoxically, Great Britain spends substantial sums (something like £300 million a year) on research to produce new knowledge, but only trifling amounts on research into ways of putting it where it can be of the widest practical use. Perhaps the time is ripe for the principal organizations representing scientists and information workers to consider jointly how the country's needs in this respect can best be met.

Leslie Wilson

Aslib,
4 Palace Gate,
London, W.8.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

### Tuesday, January 3—Wednesday, January 4

Institute of Physics, Electron Microscopy Group (in the Textile Industries Department, The University, Leeds).—Conference on "The Electron Microscopy of Textile and Other Industrial Fibres".

### Tuesday, January 3—Friday, January 6

Geographical Association (at the London School of Economics and Political Science, Houghton Street, London, W.C.2)—Annual Conference.

### Wednesday, January 4

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. P. M. Grundy, Mr. M. J. R. Healy and Mr. D. H. S. Rees: "Economic Choice of the Amount of Experimentation".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. R. L. Brown: "Some Coal Research Problems and their Industrial Implications".*

### Wednesday, January 4—Thursday, January 5

Physical Society, and the Royal Meteorological Society (in the Department of Meteorology, Imperial College, London, S.W.7), at 9.30 a.m. daily—Joint Conference on "Cloud Physics".

### Thursday, January 5

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 3 p.m.—Wing Commander R. P. Beamont: "Test Flying—Current Problems and Techniques" (Young People's Lecture).

Institute of Refrigeration (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. H. H. Egginton: "Refrigeration Controls".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Paper by the late Mr. T. Lawrie on "Highland Water Power—The Development of the North of Scotland Hydro-Electric Board" (the paper will be read by an Officer of the Board).

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. M. B. Martin and Mr. D. L. A. Smith: "Domestic Tape Recording Applications with special reference to Stereophonic Reproduction".

### Friday, January 6

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Prof. C. de Duve (University of Louvain): "Intracellular Distribution Patterns of Enzymes".* (Further Lecture on January 9.)

### Saturday, January 7

British Mycological Society (in the Large Physics Lecture Theatre, Birkbeck College, Malet Street, London, W.C.1), at 11 a.m.—London Meeting.

British Interplanetary Society (in the York Hall of Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Dr. H. P. Wilkins: "Evolution of Our Galaxy".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chemical Engineers (with a good honours degree in chemical engineering or A.R.I.C. or A.M.I.Chem.E., or equivalent qualifications) to investigate plant control techniques, and the technical performance of plant in relation to programming or flowsheeting—The Recruitment Officer, Industrial Group Headquarters, United Kingdom Atomic Energy Authority, Risley, near Warrington, Lancs (January 6).

Chief Training Officer (with a science or engineering honours degree, and a wide experience with a large industrial organization in the selection and training of scientific and technical staff) to form and operate staff training schemes for professional, scientific and non-technical staff—The Senior Recruitment Officer, United Kingdom Atomic Energy Authority, Risley, near Warrington (January 6).

Assistant Lecturer (with a degree in science or agriculture and an interest in dairy chemistry) in Chemistry—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (January 10).

Assistant Educational Psychologist (with a degree in psychology and approved clinical training) for duties consisting of advisory work in the schools and diagnostic work in the Hampshire County Council Child Guidance Clinic and Remand Homes—Education Officer, The Castle, Winchester (January 14).

Guide Lecturer (with a degree in science or engineering, preferably with lecturing experience and a knowledge of French and German) at the Science Museum, for duties including the preparation and delivery of lectures (with visual aids and practical demonstrations) on the Engineering Sections and to conduct parties round the Museum—Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4536/56 (January 14).

Assistant (with a degree in electrical engineering, and preferably with some research or industrial experience) in the Department of Engineering—The Secretary, The University, Edinburgh (January 15).

Lecturer, Grade II (graduate in mining with underground experience and preferably with some research experience) in Coal Mining—The Registrar, The University, Edgbaston, Birmingham 15 (January 16).

Livestock Research Officer (Poultry) (with a university degree with emphasis on animal nutrition) at the Poultry Experiment Station, Department of Agriculture, Seven Hills, N.S.W., Australia, to plan and undertake research work in the field of poultry nutrition—The Agent General for New South Wales, 56 Strand, London, W.C.2 (January 24).

Lecturer (with special qualifications in inorganic chemistry, including experience in teaching from elementary level upwards) in Chemistry in St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (January 31).

Head of the Chemistry Department, Senior Principal Scientific Officer grade—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (February 1).

Reader in Experimental Physics at the Royal Holloway College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 7).

Reader in Zoology at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 9).

Lecturer or Assistant Lecturer (with a special interest in physico-organic chemistry) in Chemistry—The Secretary, The University, Exeter (February 11).

Lecturer in Zoology—The Secretary, The University, Edinburgh (February 11).

Chair of Electrical Engineering at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 13).

Senior Lecturer or Lecturer in Pharmacology at the University College, Ibadan—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (February 13).

Reader in Mechanical Engineering at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 14).

Reader in Aeronautics at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 16).

Assistant Trials Officers (2) (with a degree in botany or agriculture, or equivalent qualification, with practical experience in crop production) to work at the Seale-Hayne Agricultural College, Newton Abbot, Devon, and Leeds University Farm, Headley Hall, Yorks—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Head (with a good degree in zoology and competent to undertake the planning and supervision of the filming and televising of zoological subjects) of the Television and Film Unit, Zoological Society of London and Granada T.V. Network, Ltd.—The Director and Permanent Secretary, The Zoological Society of London, Regent's Park, London, N.W.1.

Laboratory Assistant (with experience in either physical or biological laboratory work), to assist in research work involving the application of physical methods in biological problems—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks, quoting 55/25.

Master to take charge of the Science Department and advise on the building and equipment of new laboratories—The Headmaster, Berkhamsted School, Herts.

Produce Officer (with a university degree in agriculture or economics or a national diploma in agriculture, with experience in the handling of agricultural products, particularly grading inspection and storage, and some knowledge of prevention and control of pest infestation of stored products) with the Government of the Northern Region, Nigeria—Crown Agents, 4 Millbank, London, S.W.1, quoting M1B/42896/TA.

Research Assistant (with an honours degree in metallurgy, physics or chemistry) to the Joseph Lucas Research Fellow, to undertake research on the structure and mechanical properties of electrodeposits—Department of Industrial Metallurgy, The University, Birmingham 15.

Research Officer (with a university degree in forestry, or a university degree in botany and a diploma in forestry) in the Department of Forest Research, Federation of Nigeria, to carry out sylvicultural investigation, chiefly in the highest forest regions of the Federation, but with a possibility of work in the savannah regions also—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.61/14/06.

Scientist (with a good degree in chemistry or physics, or equivalent qualification, analytical experience and administrative ability), as a deputy to the Area Chief Scientist, Cannock Chase Area Laboratory, for work covering a wide field involving the analysis of coal, water, mine air and stores testing (oil, etc.)—The Divisional Establishment Officer, National Coal Board, Himley Hall, Dudley, Worcs.

# REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

### Great Britain and Ireland

Science Masters' Association. Report of the Sub-Committee on Laboratory Technicians, 1955. Pp. 16. (London: John Murray (Publishers), Ltd., 1955. Published for the Science Masters' Association.) 1s. 2d., post free. [2110

University of Birmingham Metallurgical Society. Annual Newsletter. Fiftieth Anniversary Edition, 1955. Pp. viii+44. (Birmingham: University of Birmingham Metallurgical Society, 1955.) [2110

Commonwealth Agricultural Bureaux. Notes on Progress in the Agricultural Sciences, 1953–54. Pp. 24. (London: H.M. Stationery Office, 1955.) 2s. net. [2110

Department of Scientific and Industrial Research. Building Research Station. National Building Studies—Research Paper No. 22: Studies in Composite Construction. Part 2: The Interaction of Floors and Beams in Multi-Story Buildings. By Dr. R. H. Wood. Pp. vii+124+8 plates. (London: H.M. Stationery Office, 1955.) 5s. net. [2210

Readers' Guide to Books on Electrical Engineering (New Series—No. 29, August, 1955.) Pp. 36. (London: Library Association, 1955.) 1s. [2510

Institution of Electrical Engineers. List of Members. Part 1: Corporate Members and Companions. Pp. 579. (London: Institution of Electrical Engineers, 1955.) [2510

Royal Institute of Chemistry. Lectures, Monographs and Reports, 1955. No. 4: Chemical Aspects of Oceanography. By Dr. H. Barnes. Pp. ii+29. (London: Royal Institute of Chemistry, 1955.) 4s 6d. [2510

Agricultural Research Council: Soil Survey Research Board. Report No. 7, 1954. Pp. iv+38. (London: H.M. Stationery Office, 1955.) 4s. 6d. [2510

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 945, Vol. 248 (20 October 1955): The Moments of the Number of Points of a Lattice in a Bounded Set. By C. A. Rogers. Pp. 225–251. 8s 6d. No. 946, Vol. 248 (20 October 1955): An Assessment of the System of Optimum Coding Used on the Pilot Automatic Computing Engine at the National Physical Laboratory. By J. H. Wilkinson. Pp. 253–281. 9s. (London: Royal Society, 1955.) [2510

Proceedings of the West African International Cacao Research Conference held at the West African Cacao Research Institute, Tafo, Gold Coast, 12th to 16th December, 1953. Pp. vii+100. (London: Crown Agents for Oversea Governments and Administrations, 1955.) 12s. 6d. [2510

Gurr's Quick Reference Laboratory Notes: Directions for Preparing Solutions from Compound Stains. Second edition. Pp. 6. Gurr's Commentary on Current Laboratory Methods. No. 16. (September, 1955.) Pp. 59–62. (London: George T. Gurr, Ltd., 1955.) [2610

The Sources of Animal Behaviour. By Prof. G. P. Wells. (An Inaugural Lecture delivered at University College London, 5 May, 1955.) Pp. 20. (London: H. K. Lewis and Co., Ltd., 1955.) 2s. 6d. [2610

Hull Bulletins of Marine Ecology. Edited by A. C. Hardy and Dr. C. E. Lucas. Vol. 3. Pp. i-ix. (June, 1955): Title Page, Contents Table, List of Personnel, Explanation. (Hull: At the University College, 1955.) 2s. 6d. [2610

Department of Scientific and Industrial Research and Fire Offices' Committee. (Joint Fire Research Organization.) References to Scientific Literature on Fire. Part 7, 1953. By Miss H. M. Shakeshaft and Mrs. B. F. W. Rogowski. Pp. 122. List of Reports etc. published by H.M. Stationery Office and in Technical Journals. (August, 1955.) Pp. 11. (Boreham Wood, Herts: Fire Research Station, 1955.) [2710

Ministry of Agriculture, Fisheries and Food. Report on the Animal Health Services in Great Britain, 1954, including Report of Proceedings under the Diseases of Animals Act, 1950. Pp. iv+106. (London: H.M. Stationery Office, 1955.) 4s. net. [2710

Institute of Personnel Management. Annual Report, 1954–55. Pp. 20. (London: Institute of Personnel Management, 1955.) [2710

*Planning*. Vol. 21. No. 387 (24 October 1955): Graduates' Jobs. Pp. 193–208. (London: Political and Economic Planning, 1955.) 2s. 6d. [2710

Agricultural Research Institute of Northern Ireland. Twenty-eighth Annual Report, 1954–55. Pp. 37. (Hillsborough, Co. Down: Agricultural Research Institute of Northern Ireland, 1955.) [2810

International Association for the Exchange of Students for Technical Experience. Eighth Annual Report (November, 1955). Pp. 84. (London: International Association for the Exchange of Students for Technical Experience, 1955.) [2810

Queen's University of Belfast. The Anatomy of the Cold War. By Salvador de Madariaga. (Montague Burton Lecture on International Relations, delivered in the Queen's University of Belfast on April 21, 1955.) Pp. 27. (Belfast: Marjory Boyd, Printer to the Queen's University of Belfast, 1955.) 6d. [2810

A Scientist In and Out of the Civil Service. By Sir Henry Tizard. (The Twenty-second Haldane Memorial Lecture delivered at Birkbeck College, London, 9th March 1955.) Pp. 21. (London: Birkbeck College, 1955) [2810

## Other Countries

*Giornale di Microbiologia*. Vol. 1, No. 1 (Luglio-Agosto, 1955). Pp. 96+10 plates. Abbonamenti: Italia—il volume di sei numeri L. 2500. Estero L. 3000. Numero separato L. 500. (Milano: Casella Postale 3279. Viale Italia 74–76.) [2110

Reports of the Haffkine Institute, Bombay. For the years 1942 and 1943. By Major-General Sir Sahib Singh Sokhey. Pp. ii+60. Annas 6; 6d. For the years 1944–1946. By Major-General Sir Sahib Singh Sokhey. Pp. iii+85. Annas 5; 6d. For the years 1947–1948. By Major-General Sir Sahib Singh Sokhey. Pp. ii+77. Annas 7; 9d. For the year 1949. By Dr. P. M. Wagle. Pp. ii+56. Rs. 1; 1s. 8d. For the year 1950. By Dr. P. M. Wagle. Pp. iii+60. Rs. 2; 4s. For the year 1951. By Dr. P. M. Wagle. Pp. ii+59. Rs. 1/7/-; 2s. 6d. For the year 1952. By Dr. P. M. Wagle. Pp. ii+74. Annas 5; 6d. For the year 1953. By Dr. P. M. Wagle. Pp. iii+88. Annas 7; 9d. (Bombay: Superintendent, Government Printing and Stationery; London: High Commissioner for India, 1948–55.) [2210

Scientific Reports of the Indian Agricultural Research Institute for the year ending 30th June, 1954. Pp. 127. (Delhi: Manager of Publications, 1955.) [2210

Tanganyika: Geological Survey Department. Report No. 1: The Tunduru-Ruvuma Area of the Southern Province—a Reconnaissance of the Geology, Soils, Vegetation and Hydro-electric Potential. By Dr. D. R. Grantham. Pp. iii+14+1 map. Shs. 3. Bulletin No. 24: The Soils of Mbozi (Mbeya District)—a Study in Relation to the Geology and Physiography. By A. M. M. Spurr. Pp. vii+35+4 plates+3 maps. Shs. 7/50. (Dar-es-Salaam: Government Printer, 1955.) [2210

Publications de l'Institut National pour l'Étude Agronomique du Congo Belge. Série Technique, No. 45: Le Ravitaillement en Calcium et en Phosphore et le Comportement du Squelette du Bétail au Congo Belge. Par Prof. L. Hennaux et R. Compère. Pp. 45+6 plates. (Bruxelles: Institut National pour l'Étude Agronomique du Congo Belge, 1955.) 60 francs. [2210

Chicago Natural History Museum. Fieldiana: Botany. Vol. 29, No. 2: Revision of the Hawaiian Members of the Genus Tetraplasandra A. Gray. By Earl Edward Sherff. (Publication 749.) Pp. ii+49–142. 1.50 dollars. Fieldiana: Anthropology. Vol. 44, No. 2: Old Akkadian Inscriptions in Chicago Natural History Museum—Texts of Legal and Business Interest. By Ignace J. Gelb. (Publication 748.) Pp. iv+161–338. 5 dollars. Fieldiana Zoology. Vol. 37: Karl Patterson Schmidt Anniversary Volume in Honor of his Sixty-fifth Birthday. (Publication 747.) Pp. viii+728. 10 dollars. (Chicago: Chicago Natural History Museum, 1955.) [2510

International Scientific Radio Union. Proceedings of the 11th General Assembly held in The Hague from August 23rd to September 2nd 1954. Vol. 10, Part 3: Commission 3 on Ionospheric Radio. Pp. 194. (Bruxelles: International Scientific Radio Union, 1955.) 200 francs; 29s.; 4 dollars. [2510

Shooting Stars. By Prof. Hans Pettersson. Pp. 16. (Särtryck ur Sjöfartsmuseets i Göteborg festskrift för Tor E. J:son Broström, 1955.) [2510

Fisheries Research Board of Canada. Progress Reports of the Atlantic Coast Stations. No. 62 (July, 1955). Pp. 43. General Series Circular No. 26 (July, 1955): Watch for the Green-Crab—a New Clam Enemy. By J. C. Medcof and L. M. Dickie. Pp. 1. (Ottawa: Fisheries Research Board of Canada, 1955.) [2510

British Guiana. Geological Survey Bulletin No. 25: The Geology of British Guiana and the Development of its Mineral Resources. Compiled from Geological Survey Records by G. M. Stockley. Pp. 102+6 plates. (Georgetown: Geological Survey, 1955.) 3 dollars; 12s. 6d. [2510

National Research Council of Egypt. Bulletin of the Scientific and Technical Documentation Centre. Vol. 1, No. 1 (July, 1955): Part 2—Abstracts of Scientific and Technical Papers published in Egypt, and papers received from Afghanistan, Cyprus, Iran, Iraq, Lebanon, Pakistan, Sudan and Syria. Edited with the collaboration of the Unesco Middle East Science Cooperation Office, Cairo. Pp. 13. (Cairo: National Research Council of Egypt, 1955.) [2510

List of Scientific Papers published in the Middle East (Afghanistan, Cyprus, Egypt, Iran, Iraq, Israel, Lebanon, Pakistan, Sudan, Syria and Turkey). No. 12 (July, 1955). Pp. v+130. (Cairo: Middle East Science Cooperation Office, 1955.) [2510

Pubblicazioni dell' Università Cattolica del S Cuore. Nuova Serie. Vol. 51: Annali della Facoltà di Agraria—Serie Prima. Pp. vii+498. 4000 lire. Vol. 52: Annali della Facoltà di Agraria—Serie Seconda. Pp. vii+451. 4000 lire. (Milano: Società Editrice "Vita E Pensiero", 1955.) [2510

The Carlsberg Foundation's Oceanographical Expedition Round the World, 1928–30, and previous "Dana" Expeditions, under the leadership of the late Prof. J. Schmidt. Dana Report No. 41: The Fishes of the Genus Tetragonurus. By Marion Grey. Pp. 75. (Copenhagen: Andr. Fred. Høst and Son, 1955. Published by the Carlsberg Foundation.) 20 kroner; 20s. [2510

Bechuanaland Protectorate: Geological Survey Department. Annual Report for 1954. Pp. 40. (Lobatsi: Geological Survey, 1955) 3s. [2610

Provincia do Mocambique. Servicos de Industria e Geologica. Série de Geologica e Minas—Memorias e Communicacoes. Boletim No. 14: Estudos Geoquimicos das Aguas Superficiais e Subterraneas das Rochas Sedimentares do Sul do Save. Por Vero Louis Bosazza. Pp. 46+3 plates. (Lourenco Marques: Artes Graficas, Lda., 1954.) [2810

Smithsonian Institution: Bureau of American Ethnology. Bulletin 157: Anthropological Papers Nos. 43–48. Pp. iii+415+76 plates. 2.75 dollars. Bulletin 158: River Basin Survey Papers. Inter-Agency Archeological Salvage Program. No. 7: Archeological Investigations in the Oahe Dam Area, South Dakota, 1950–51. By Donald J. Lehmer. Pp. xi+190+22 plates+6 maps. 1.50 dollars. Bulletin 159: The Horse in the Blackfoot Indian Culture, with Comparative Material from Other Western Tribes. By John C. Ewers. Pp. xv+374+17 plates. 2.75 dollars. Bulletin 160: A Ceramic Study of Virginia Archeology. By Clifford Evans. With Appendix—An Analysis of Projectile Points and Large Blades. By C. G. Holland. Pp. viii+195+30 plates. 1.25 dollars. Seventy-first Annual Report, 1953–54. Pp. ii+17. (Washington, D.C.: Government Printing Office, 1955.) [2710

Smithsonian Institution. Freer Gallery of Art. Occasional Papers. Vol. 2, No. 2: Abstracts of Technical Studies in Art and Archaeology, 1943–1952. Compiled by Rutherford J. Gettens and Bertha M. Usilton. (Publication 4176.) Pp. viii+408. (Washington, D.C.: Smithsonian Institution, Freer Gallery of Art, 1955.) [2710

Indian Forest Bulletin (New Series). No. 188: Cellulose and Paper. Indigenous Cellulosic Raw Materials for the Production of Pulp, Paper and Board. Part 23: Chemical Pulps and Writing and Printing Papers from *Saccharum procerum* Roxb. (*[illegible]*). By R. V. Bhat and Narendra S. Jaspal. Pp. ii+9. (Delhi: Manager of Publications, 1955.) 12 annas; 1s. [2710

Forest Research in India, 1950–51. Part 1: The Forest Research Institute. Pp. iii+127. (Delhi: Manager of Publications, 1955.) Rs. 9/8/-; 15s. [2710

Gold Coast Department of Soil and Land-Use Survey. Memoir No. 1: Detailed Soil Survey of the Kpong Pilot Irrigation Area. By H. Brammer. Pp. 102+9 maps. (Accra: Government Printer; London: Crown Agents for Oversea Governments and Administrations, 1955.) 10s. [2710

Northern Region of Nigeria. Annual Report of the Forestry Department, 1953–54. Pp. i+34. (Lagos: Government Printer; London: Crown Agents for Oversea Governments and Administration, 1955.) 9d. [2610
